About this edition

This volume contains Alexander Grothendieck's research notes of 1981, held in the Montpellier archive: cote 140-1, a draft (37 scans); cote 140-2, manuscript pages 1–292 (575 scans); cote 140-3, pages 293–650 (696 scans); and cote 140-4, pages 650bis–787 (280 scans). All 116 packages and all 245 translation units are included in scan order. This edition works from the supplied transcription, translation and checking records; it proposes no new reading of the handwriting.

The corrected text follows the author's explicit final state. Cancelled words leave the running text; insertions are integrated and shown in teal. Every difference is recorded in the annotated master. The translation follows the supplied English package texts and glossary, with one documented correction from "structure with loops" to "loop structure". The author's letters, indices, arrows and forms such as Sl, Gl, Autext and the doubled Γ remain unchanged. Doubtful and illegible readings are retained.

The apparatus at the end of each scan gives the manuscript reading, the adopted text, the kind of intervention and its reason. Small d and i references identify deletions and insertions within the scan. Revisions entirely inside a cancelled passage belong to that cancellation's entry. The apparatus supplies no mathematical commentary.

Every blue passage, red [illeg. n] marker and scan mark links to its scan in the Montpellier viewer. A marginal note stays in the margin when it fits the note column in at most three lines. Longer notes appear at their insertion point in the text block, in small type, with a rule and the label *Marginal note*. Wide formulae and diagrams have repairs at identified source locations. Diagrams needing more room appear on landscape pages.

Production and credits

AI-transcribed by GPT-6 Astra (OpenAI, ChatGPT Pro mode), checked against the scans by Claude Opus 5.5 (Anthropic).

AI-translated by GPT-6.1 Sol (OpenAI, reasoning effort max, API Flex tier); prompts, checks and fixes by Claude (Anthropic).

this edition built by GPT-6 Astra (OpenAI, ChatGPT Pro mode).

The earlier glossary was prepared by Claude Opus 5.5 and Claude Fable 5.2 (Anthropic). The earlier transcription and translation build, checks and repairs are credited to Claude (Anthropic) in their source records.

Sources and earlier work

Université de Montpellier, Institut Montpelliérain Alexander Grothendieck, archives Grothendieck. `https://grothendieck.umontpellier.fr/archives-grothendieck/`

Earlier transcriptions were consulted in the second pass as witnesses and are not reproduced here.

- Mateo Carmona's edition of the first part, transcribed from the typescript, and the typeset text deciphered and transcribed by Mateo Carmona with the collaboration of Matthias Künzer (agrothendieck.github.io).
- the draft edition of the Centre for Grothendieckian Studies (Grothendieck Institute, Mondovì), February 2026.
- the table of contents compiled by Grothendieck himself, as published by the Grothendieck Circle.

Rights

The rights in the original work belong to its author or the author's representatives or heirs. Where we hold rights, in the AI-produced transcription, translation, corrections and typesetting, they are dedicated to the public domain under CC0 1.0. This edition is published for educational, non-profit purposes, and we claim no rights we do not hold. If you hold rights in this work and object to its publication here, please open a GitHub issue and we will take it down.

[scan 4]

[p. 1]

$$\widetilde{\Pi}_n^{\circ D}|\widetilde{\Pi}_n^{D}\simeq\,|\,=\{\tilde\rho,\tilde\sigma\mid \tilde\rho^n=\tilde\sigma^2\}\qquad \boxed{\tilde\rho^n=\tilde\sigma^2=\tilde\omega_0}\quad \text{central element}$$

$$1\to\mathbb{Z}\to\widetilde{\Pi}_n^{\circ D}|\widetilde{\Pi}_n^{D}\;\text{—}\;\Pi_n^{D}\;\text{—}\;1$$

central extension

Let us put

$$\boxed{\tilde\rho_0=\tilde\sigma\tilde\rho\tilde\sigma^{-1}\tilde\rho}=\tilde\sigma(\tilde\rho)\tilde\rho$$
$$=(\tilde\sigma\tilde\rho)^2\tilde\omega_0^{-1}$$

$$\boxed{\tilde\rho_i=\tilde\rho^i(\tilde\rho_0)}$$

$\tilde\rho_i$ lifts ρ_i

We have

$$\tilde{\rho}_{n-1}\tilde{\rho}_{n-2}\cdots\tilde{\rho}_0 = \underbrace{\tilde{\rho}^{n-1}\tilde{\rho}_0\tilde{\rho}^{-(n-1)}}\,\underbrace{\tilde{\rho}^{n-2}\tilde{\rho}_0\tilde{\rho}^{-(n-2)}}\cdots(\tilde{\rho}\tilde{\rho}_0\tilde{\rho}^{-1})\tilde{\rho}_0$$

$$= \tilde{\rho}^{n-1}\tilde{\rho}_0\tilde{\rho}^{-1}\tilde{\rho}_0\tilde{\rho}^{-1}\cdots\tilde{\rho}^{-1}\tilde{\rho}_0\tilde{\rho}^{-1}\tilde{\rho}_0 \qquad (n \text{ factors } \tilde{\rho}_0$$

$$= \tilde{\rho}^n\,\underbrace{(\tilde{\rho}^{-1}\tilde{\rho}_0)\cdots(\tilde{\rho}^{-1}\tilde{\rho}_0)}_{n \text{ factors}} = \underbrace{\tilde{\rho}^n}_{\tilde{\omega}_0}(\tilde{\rho}^{-1}\tilde{\rho}_0)^n$$

now

$$\tilde{\rho}^{-1}\tilde{\rho}_0 = \tilde{\rho}^{-1}\tilde{\sigma}\tilde{\rho}\tilde{\sigma}^{-1}\tilde{\rho} = (\tilde{\rho}^{-1}\tilde{\sigma})(\tilde{\rho})$$

. therefore

$$(\tilde{\rho}^{-1}\tilde{\rho}_0)^n = (\tilde{\rho}^{-1}\tilde{\sigma})(\tilde{\rho}^n) = (\tilde{\rho}^{-1}\tilde{\sigma})(\tilde{\omega}_0) = \tilde{\omega}_0$$

whence

$$\boxed{\tilde{\rho}_{n-1}\tilde{\rho}_{n-2}\cdots\tilde{\rho}_0 = \tilde{\omega}_0^2}$$

Let $\widetilde{\Pi}_n$ be d4 the inverse image of $\Pi_n \subset \Pi_n^D$ in $\widetilde{\Pi}_n^D$i1 d5

$$1 \text{ — } \mathbb{Z} \longrightarrow \widetilde{\Pi}_n \longrightarrow \Pi_n \text{ — } 1$$

$$\widetilde{\Pi}_n = \left\{ \tilde{\rho}_0, \ldots, \tilde{\rho}_{n-1}, \tilde{\omega}_0 \;\middle|\; \begin{array}{l} \tilde{\omega}_0 \text{ central,} \\ \tilde{\rho}_{n-1}\tilde{\rho}_{n-2}\cdots\tilde{\rho}_0 = \tilde{\omega}_0^2 \end{array} \right\}$$

Let $\tilde{\rho}|\rho$

$$\widetilde{\Pi}_n^\circ = \left\{ \tilde{\rho}_0, \ldots, \tilde{\rho}_{n-1} \;\middle|\; \begin{array}{l} \tilde{\rho}_{n-1}\tilde{\rho}_{n-2}\cdots\tilde{\rho}_0 \text{ central} \quad \text{i.e.} \\ \tilde{\rho}_{n-1}\tilde{\rho}_{n-2}\cdots\tilde{\rho}_0 = \tilde{\rho}_{n-2}\tilde{\rho}_{n-3}\cdots\tilde{\rho}_0\tilde{\rho}_{n-1} = \cdots \end{array} \right\}$$

Then

$$1 \text{ — } \mathbb{Z} \text{ — } \widetilde{\Pi}_n^\circ \text{ — } \Pi_n \text{ — } 1$$

generated by

$$\bar{\omega} = \tilde{\rho}_{n-1}\tilde{\rho}_{n-2}\cdots\tilde{\rho}_0$$

$$\widetilde{\Pi}_n \simeq \,|\, \subset \widetilde{\Pi}_n^\circ \underset{\mathbb{Z}\bar{\omega}}{\wedge} \mathbb{Z}\omega$$

$$\bar{\omega}_0 \to \omega_0^2$$

[p. 4] m15

Marginal note. m15 (n odd)

Proposition There exist liftings $\tilde\rho, \tilde\sigma$ of ρ, σ such that we have $\tilde\rho^n = \tilde\sigma^2$ d1, and the two sides are then of the form $\widetilde{\omega}^\nu$, one of the i1 d2, ν well-defined quantity|† d3 modulo $2n$ (independently of the choices of the liftings $\tilde\rho, \tilde\sigma$) and $\nu \equiv \dfrac{n^2+1}{2}$ d4, or :

$$\nu \bmod 2n \ \in \left\{ \left(-\frac{n-1}{2}, \frac{n+1}{2}\right) \right\}$$

and ν is odd. Which implies that there exists a ν_0 unique in $\left\{-\dfrac{n-1}{2}, \dfrac{n+1}{2}\right\}$ that is $\equiv \nu\ (2n)$. For ν fixed, $\tilde\rho, \tilde\sigma$ are uniquely determined. Thus we find|This provides presentation

$$\widetilde{\Pi}_n^D = \{\tilde\rho, \tilde\sigma, \widetilde{\omega} \mid \widetilde{\omega} \text{ central}, \ \tilde\rho^n = \tilde\sigma^2 = \widetilde{\omega}^{\nu_0|\nu}\}\,.$$

[scan 16]

[p. 5]

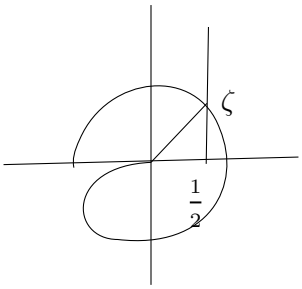
$M_{1,1} \simeq (U_{0,3}, \mathbb{D}'_3)$, where $\mathbb{D}'_3$ is defined as the fiber product

$$\begin{array}{ccc} \mathbb{D}_3 = \mathfrak{S}_3|\mathfrak{G}_3 & \xrightarrow{\text{can}} & \mathbb{Z}/2\mathbb{Z} \\ \uparrow & & \uparrow \text{can} \\ \mathbb{D}'_3 & \longrightarrow & \mathbb{Z}/4\mathbb{Z} \end{array}$$

so $\mathbb{D}'_3$ is an extension (nontrivial|quite trivial) of $\mathbb{D}_3$ by $\mathbb{Z}/2\mathbb{Z}$; [d1] we let $\mathbb{D}'_3$ act on $U_{0,3}$ via $\mathbb{D}_3$, so with triviality of the element ω of order 2 of the kernel of $\mathbb{D}'_2|\mathbb{D}'_3 \to \mathbb{D}_2|\mathbb{D}_3$. to be checked OK

We thus have

$$\begin{array}{ccc} \mathcal{T}_{11} & \simeq & \Pi_1 \overbrace{(U_{0,3}, \mathbb{D}'_3; P_+)}^{\Pi^{\mathbb{D}'_3}_{0,3}} \\ \wr & & \\ \mathrm{S}\ell(2,\mathbb{Z}) & & \end{array}$$



m22

Marginal note. m22 depends on the choice of a point of the Poincaré half-plane above P_+, we will take|or take $\zeta = \exp(2i\pi/6)$ a

and thus

m23

Marginal note. m23 $\Pi_\rho|\Pi_0$ $\Pi_{0,3}$

$$\begin{array}{ccc} \Pi^{\mathbb{D}'}_{0,3} & \longrightarrow & \Pi^{\mathbb{D}}_{0,3} = \{\rho, \sigma \mid \rho^3 = \sigma^2 = 1\} \\ \downarrow & \text{cart} & \Downarrow \\ \mathbb{D}'_3 & \longrightarrow & \mathbb{D}_3 \\ \downarrow & \text{cart} & \downarrow \\ \mathbb{Z}/4\mathbb{Z} & \longrightarrow & \mathbb{Z}/2\mathbb{Z} \end{array}$$

m25

$\rho \mapsto 0$
$\sigma \mapsto 1$

Marginal note. m25 We lift ρ, σ to ρ', σ'
$\rho' = (\rho, 2), \quad \sigma' = (\sigma, 3)$
we have $\rho'^6 = \sigma'^4 = 1$,
$\rho'^3 = \sigma'^2 = (\underbrace{1, 2 \bmod 4}_{\omega})$.

m26

Marginal note. m26 We then easily verify that
$\mathrm{S}\ell(2,\mathbb{Z}) \simeq \{\rho', \sigma' \mid \rho'^6 = \sigma'^4 = 1,\ \rho'^3 = \sigma'^2\}$.

m27

Marginal note. [m27]

Thus $\Pi^{\mathbb{D}'}_{0,3} \simeq \mathrm{S}\ell(2,\mathbb{Z})$ appears as an extension of $\Pi^{\mathbb{D}}_{0,3}$ by $\mathbb{Z}/2\mathbb{Z}$, inverse image [d7] the extension $\mathbb{D}'_3$ [i4] of $\mathbb{D}_3$ by $\mathbb{Z}/2\mathbb{Z}$, or of the extension $\mathbb{Z}/4\mathbb{Z}$ of $\mathbb{Z}/2\mathbb{Z}$ by $\mathbb{Z}/2\mathbb{Z}$, via $\Pi^{\mathbb{D}}_{0,3} \to \mathbb{D}_3$ resp. composite $\Pi^{\mathbb{D}}_{0,3} \to \mathbb{Z}/2\mathbb{Z}$. It is an extension of $\mathbb{D}'_3$ by a group $\simeq \Pi_{0,3}$, with basis $\rho_0, \rho_1, \rho_\infty$ — 15

[scan 22]

[scan 23]

A) Lemma S [d1] regular integral scheme such that $\mathrm{Pic}(S) = 0$, characteristic of the generic point $\neq 2$ Then [d2]

$$H^1(U_{0,3}, \mathfrak{S}_3; \mathbb{G}_m] \simeq \mathbb{Z}/6\mathbb{Z}$$

([d3]generic point|if generic[i1] is 2, we find $\mathbb{Z}/3\mathbb{Z}$)
[m39]

Marginal note. [m39] Proof we use exact sequence

$$0 \longrightarrow H^1(\mathfrak{S}_3, H^0(U_{0,3}, \mathbb{G}_m) \longrightarrow H^1(\text{mixed})$$
$$H^0(\mathfrak{S}_3, \underbrace{H^1(U_{0,3}; \mathbb{G}_m)}_{0})$$

and

$$0 \to H^0(S, \mathbb{G}_m) \to H^0(U_{0,3}, \mathbb{G}_m) \to h_1(V(J))|h^1(V(J)) \to 0$$

I say that if the scheme[i2] Σ_J is defined as $\mathbb{P}(V_J)$, i.e.

$$0 \longrightarrow V_J \longrightarrow \mathcal{O}^J \longrightarrow \mathcal{O} \longrightarrow 0$$

then the principal bundle

$$P\Sigma_J = \check{V}(\mathcal{O}_{\Sigma_J}(1))^*$$

is a generator of the $H^1(\Sigma_J^*, \mathfrak{S}_J; \mathbb{G}_m)$.

I will first find a trivialization of

$$\underline{\mathcal{O}}(1)^{\otimes 6} = \mathcal{O}(6) \simeq \mathcal{T}^{\otimes 3}(\omega)|\mathcal{J}^{\otimes 3}(\omega),$$

[d7] in fact[i6] a section of $\mathcal{O}(6)$ over $\overline{\Sigma}$ in its entirety[i7] (which [d8] is, invertible[i8] on Σ^*. We [d9] have

$$\Gamma(\Sigma_J, \mathcal{O}(6)) \simeq \mathrm{Sym}^6 V_J$$

and we will take

$$\varphi|\Delta \in \Gamma(\Sigma_J, \mathcal{O}(6)), \qquad \varphi|\Delta = -\prod_{\substack{i,j\in J \\ i\neq j}} (e_i - e_j)$$
$$= \prod_{i\in J} \underbrace{(e_j - e_h)^2}_{J=\{i,j,h\}}.$$

Thus, over Σ_J^*, the structure|structure group [d12] $\mathbb{G}_m$ of $P\Sigma_J^*$ is reduced to|: μ_6.

N.B. Unless I am mistaken, we have

$$\mathrm{Sym}^*(V_J)^{\mathfrak{S}_3} \simeq \mathcal{O}(\gamma_2|\varphi_2, \gamma_3|\varphi_3)/(2\gamma_3^2 - \gamma_2^3)$$

$$\begin{cases} \gamma_2 = \sum_{i\in J} (e_j - e_h)^2 \\ \gamma_3 = \prod_{i\in J} (e_j - |+ e_h - 2e_i) \end{cases} \qquad \text{and} \quad \Delta = \gamma_2^3$$

Since γ_2 vanishes at d4 P_ω, γ_3 at the Q_i, it follows that there is no invariant section of an $\mathcal{O}(n)^*$ d5 over Σ^*_J d6 for $n \leq 6$, hence that the order of $\mathrm{cl}(\mathcal{O}(1))$ in $H^1(\Sigma_J, \mathfrak{S}_J; \mathbb{G}_m)$ is indeed 6, which proves that $\mathcal{O}(1)$ is a generator of the mixed H^1. 24

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

140-1-s030-D010 *deletion. Manuscript:* We have seen that an orientation of a combinatorial cellular|cellulation surfacemap A gives rise to|: two operators|operations $\vec{\rho}_s, \vec{\rho}_f$ on $\vec{A}$, satisfying

$$\vec{\rho}_s^{-1}\vec{\rho}_f = \sigma$$

If we take the opposite orientation, what|what are the corresponding|corresponding operators|operations $\vec{\rho}'_s, \vec{\rho}'_f$? If $\vec{a} \in \vec{A}$ comes from $a \in A^L_+$, it comes from $\sigma_n a \in A^L_-$, and we have

$$\rho_s(\sigma_n a) = \sigma_n(\underbrace{\sigma_n \rho_s \sigma_n}_{\sigma_n \varepsilon = \rho_s^{-1}} a) = \sigma_n(\rho_s^{-1} a) -$$

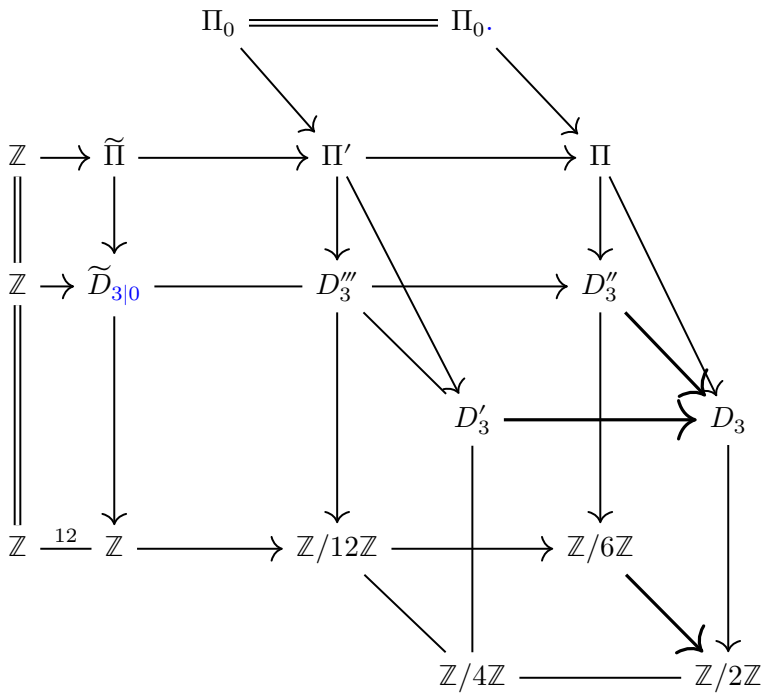
thus the class in $\vec{A} \simeq A^L/\sigma_n$ is that of $\rho_s^{-1} a$, i.e. $\vec{\rho}_s^{-1}\vec{a}$. And we therefore have

$$\rho_f(\sigma_n a) = \sigma_n(\underbrace{\sigma_n \rho_f \sigma_n}_{\sigma_n \varepsilon \sigma} a)$$

$$\vec{\rho}'_s = \vec{\rho}_s^{-1}$$

hence

$$\vec{\rho}'_f = \vec{\rho}'_s \sigma = \vec{\rho}_s^{-1}\sigma = \sigma \vec{\rho}_f^{-1}\sigma = \mathrm{int}(\sigma)\vec{\rho}_f^{-1}$$



(This is not so pleasant.)

[p. 1]

1. Multi-Galois topoi.

Proposition 1.1. Let $\mathcal{E}$ be a category. Equivalent conditions:

a) $\mathcal{E}$ is a topos, and every object of $\mathcal{E}$ is local^{ly} constant.

b) $\mathcal{E}$ is equivalent to a category $\widehat{C}$, where C is a groupoid.

m74

Marginal note. m74 N.B. We shall see (below) that we can choose C canonically

b') $\exists$ a family $(G_i)_{i\in I}$ of groups and an equivalence of categories

$$\mathcal{E} \approx \prod \mathrm{Ens}(G_i)$$

c) Ad-hoc exactness conditions, of the type of those given in SGA 1...

Proof. $b \iff b' \implies a$ immediate. For $a) \implies b)$, I am less sure, perhaps one has to assume that $\mathcal{E}$ is locally connected, and that it has sufficiently many fiber functors i.e. sufficiently many points.

Definition 1.2. If the equivalent conditions b) b') above are satisfied, one says that C is a|a multi-Galois d1 topos i1 (or a multi-Galois category).

m75

Marginal note. m75 Proposition 1.3 a) If $\mathcal{E}$ is multi-Galois, every induced topos $\mathcal{E}_{/S}$ too.
b) every sum of multi-Galois topoi (i.e. d2 product of multi-Galois categories) is so|is too.

Apparatus for this scan

[scan 7]

Proposition 1.4 Let|Let $\mathcal{E}$ be a topos, C the category of points of $\mathcal{E}$ (opposite to the category of fiber functors on $\mathcal{E}$). The canonical functor

$$\mathcal{E} \times C^o \longrightarrow (\mathrm{Ens})$$

induces a canonical functor

$$\mathcal{E} \longrightarrow \mathrm{Hom}(C^o, (\mathrm{Ens})) \overset{\text{déf}}{=} \widehat{C}$$

This being so: ($\mathcal{E}$ being multi-Galois)

a) C is a groupoid (called the "fundamental groupoid" of the multi-Galois topos $\mathcal{E}$, and often denoted $\Pi_1(\mathcal{E})$).

b) $\mathcal{E} \longrightarrow \widehat{C}$ is an equivalence of categories.

An object S i1 of a topos $\mathcal{E}$ i2 is said to be 0-connected if it is $\neq \emptyset_{\mathcal{E}}$ (it|i.e. is not an initial object) and if it is connected (i.e. $S \simeq S' \amalg S''$ implies S' or $S'' \simeq \emptyset_{\mathcal{E}}$) — this also means that the induced topos $\mathcal{E}_{/S}$ is 0-connected i.e. is not the initial topos ("empty topos", i.e. equivalent to the i3 terminal category) and that it is connected, i.e. ... One says that S is 1-connected

[p. 2]

(or "simply connected") if it is 0-connected, and if every [d1] object S' of $\mathcal{E}_{/S}$ [d2i1] locally constant is is †[d3]|constant — which depends again[i2] only on the induced topos $\mathcal{E}_{/S}$, which will then be said to be 1-connected.

Proposition 1.5. Let $\mathcal{E}$ be a multi-Galois topos, and let S be an object of $\mathcal{E}$. Equivalent conditions

a) S is 1-connected

b) S (is)|is 0-connected and projective

c) the covariant functor represented by S

$$T \longmapsto \mathrm{Hom}_{\mathcal{E}}(S, T)$$

is a fiber functor, or again as it is already left exact) it commutes with arbitrary $\varinjlim$

N.B.[i3] (it suffices that it commute with sums and with passage to the quotient...)

d) $\mathcal{E}_{/S}$ is equivalent to the point topos

e) (If $\mathcal{E} = \widehat{C}$, C a groupoid) the functor S on C is representable[i4]

Apparatus for this scan

[scan 9]

Definition 1.6 One then says, sometimes, that S (or better, the topos $\mathcal{E}_{/S}$) is a universal covering of the multi-Galois[i1] topos $\mathcal{E}$.

Proposition 1.7 [d1] Let $\mathcal{E}_0$ be[i2] the full subcategory of $\mathcal{E}$ formed by the 1-connected objects (of the multi-Galois category $\mathcal{E}$), [d2] and $\Pi_1(\mathcal{E})$ the fundamental groupoid[i3] of $\mathcal{E}$. We have by 1.5[i4] a canonical functor

$$\mathcal{E}_0 \longrightarrow \Pi_1(C)$$

(associating: $\forall\ S \in \mathrm{Ob}\,\mathcal{E}_0$ the fiber functor it represents, or rather the corresponding "point" of C), which is (not only fully faithful, but even) an equivalence of categories: every fiber functor on $\mathcal{E}$ is representable (by an essentially unique (1-connected) object, as is only right...).

[scan 13]

$$\mathcal{E} \longrightarrow \mathcal{E}_{[1]}$$

is given the name canonical morphism.

N.B. This is the equivalent in topos theory of the operation of "killing the Π_i for $i \geq 2$". One can also define an[i1] [d1] $\mathcal{E}_{[0]}$ and a sequence

$$\mathcal{E} \longrightarrow |\!-\mathcal{E}_{[1]} \longrightarrow |\!-\mathcal{E}_{[0]}$$

[$\mathcal{E}_0$ is the discrete topos defined by $\Pi_0(\mathcal{E})$, which has a satisfactory meaning as soon as $\mathcal{E}$ locally connected…]. With suitable hypotheses on $\mathcal{E}$ (of the type "local contractibility"), one should be able to define the $\mathcal{E}_{[i]}$ for $\forall\ i \in \mathbb{N}$, and canonical morphisms

$$\mathcal{E} \longrightarrow \cdots \quad \mathcal{E}_{[i]} \longrightarrow |\!-\mathcal{E}_{[i-1]} \longrightarrow \cdots \quad \mathcal{E}_{[1]} \longrightarrow \mathcal{E}_0.$$

[p. 5]

2.3. The fundamental groupoid of $\mathcal{E}$ is defined as having for objects the points of $\mathcal{E}$ (which induce points of $\mathcal{E}_{[1]}$ thanks to $\mathcal{E}_{[1]} \longrightarrow \mathcal{E}$), and for morphisms the [d1] morphisms of points of $\mathcal{E}_{[1]}$. We thus have canonical functors

$$\underline{\mathrm{Pt}}(\mathcal{E}) \xrightarrow{\alpha} \Pi_1(\mathcal{E}) \xrightarrow[\approx]{\beta} \mathrm{Pt}(\mathcal{E}_{[1]}) \overset{\text{definition}}{=} \Pi_1(\mathcal{E}_{[1]})$$

where β is an equivalence (but not surjective on objects), and where of course α is not necessarily an equivalence, nor even fully faithful, or merely faithful. For example if $\mathcal{E}$ is 1-connected i.e. $\Pi_1(\mathcal{E})$ equivalent to the one-point category, it does not necessarily follow that the Hom in|of $\mathrm{Pt}(\mathcal{E})$ are all of cardinality ≤ 1! 13

Apparatus for this scan

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 15]

Since a poin^{t} P of $\mathcal{E}$ defines a poin^{t} (still denoted P by abuse) of $\mathcal{E}_{[1]}$, one can therefore define the universal covering of $\mathcal{E}$ based at this point, as an object S^{i1} 1-connected in $\mathcal{E}_{[1]}$ – it is characterized in $\mathcal{E}^{\mathrm{i2}}$ by being locally constant, 1-connected, and endowed with a lifting

$$P \longrightarrow \mathcal{E}_{/S}.$$

But since α is not an equivalence of categories (although it is $^{\mathrm{d1}}$ essentially surjective if one assumes that $\mathcal{E}$ has enough points…) one can not say that $\forall$ universal covering of $\mathcal{E}$ is defined by a poin^{t} of $\mathcal{E}$, defined up to unique isomorphism… 14

an induction morphism. Now if $C = \Pi_1(\mathcal{E})$, $C' = \Pi_1(\mathcal{E}')$, the datum of $\mathcal{E}' \longrightarrow |-\mathcal{E}$ is equivalent to the datum of a functor $C' \longrightarrow C$. One finds that $\mathcal{E}' \longrightarrow |-\mathcal{E}$ is an induction morphism iff $C' \longrightarrow C$ is faithful. Thus, one finds an equivalence between the category $\mathcal{E}$[i1] (of objects S of the multi-Galois category $\mathcal{E} \simeq \widehat{C}$, [d5] where C is a groupoid, arbitrary if one insists) and the category whose objects are the "groupoids C' over C", with a faithful structural functor $C' \longrightarrow C$, the morphisms from C'_1 to C'_2 being the isomorphism classes of a|of a[i2] [d6] pairs (f, α) of a functor $f : C'_1 \longrightarrow |-C'_2$ and an

a bit hasty!

isomorphism of functors $\alpha : p_2 f \simeq p_1$

m85

Marginal note. [m85] Specify the isomorphisms between pairs (f, α) and [d1] (g, β)...

In the case where for example C is the category reduced to a single object, an automorphism group G, this description of the category $\mathcal{E} = \mathrm{Ens}(G)$ is obviously a bit cumbersome, but it fits well into certain contexts below.

Thus, if k is a base field, the [d2] category $\mathcal{E}$ of étale schemes over k is described, in terms of a separable closure k|the k_s of k and of the profinite group $\Gamma = \mathrm{Gal}(k_s/k)$, as the profinite[i1]

groupoids over the profinite groupoid (pt, Γ)…We want to insert this description into a "Galois" "description" of the|of [certain][i2] schemes [smooth quasi-[i3]projective of dimension ≤ 1] over k, at least if k a field of finite type over $\mathbb{Q}$. 17

define now.

Lemma 5.2. Let Ω be an algebraically closed field, X a [d1] smooth[i1] projective algebraic curve, connected over Ω, S a finite subset of $X(\Omega)$, g the genus of X, $n = \operatorname{card} S$.[i2] $U = X \setminus S$, Equivalent conditions

a) $\Pi_1(U)$ nonabelian

b) $\operatorname{Aut}(U)$ finite

c) For $\forall$ connected [d3i4] reduced scheme X of finite type[i5] over Ω, the set of nonconstant morphisms from X to U is finite

d) We are [d4] in one of the following three cases: 1°) [d5] $g \geq 2$ 2°) $g = 1$, $n \geq 1$ 3°) $g = 0$, $n \geq 3$.

m90

Marginal note. [m90] e) (if $\Omega \in | \subset \mathbb{C}$) The universal covering of $X(\mathbb{C}) \setminus S(\mathbb{C})$ is isomorphic to the half-plane of Poincaré.

m91

Marginal note. [m91] ?!|?? f) (if $\Omega = \overline{\mathbb{Q}}$ $S \neq \emptyset$) The universal covering of $X \setminus S = U$ is isomorphic to that of $\mathbb{P}^1_\Omega \setminus \{0, 1, \infty\}$.

Definition 5.3. We then say that (X, S) is anabelian. [d6]

As this condition is (by d) for example) invariant under extension of the algebraically closed base field, we extend this definition to the case of a pair (X, S), with (X, S) [d7] as in (5.1)[i6] (N.B. we look separately at the connected components of $X_{\overline{K}}$...). 19

[scan 21]

From now on, in (5.1) we are going to confine ourselves to the case of anabelian pairs (X, S). d1

5.4. To a pair (X, S) (not necessarily anabelian) — more generally to $\forall$ scheme X locally of finite type over $S|\xi$, we associate an object "of a Galois nature", namely the fundamental groupoid (profinite)[i1] $\Pi_1(X)$ of X (formed if we like of the universal coverings of X), equipped with the canonical [d2] homomorphism[i2]

$$\begin{array}{ccc} \Pi_1(X) & \longrightarrow & \Pi_1(K) \\ & & \simeq\downarrow \\ & & [\mathrm{Tors}(\Gamma)] \end{array}$$

A morphism of K-schemes

$$X' \xrightarrow{f} X$$

defines a functor

$$\Pi_1(X') \xrightarrow{\Pi_1(f)} \Pi_1(X)$$

and a commutation isomorphism α 20

We thus find a functor, from the category of schemes X locally of finite type over K, into the "category of profinite groupoids over $\Pi_1(K)$", defined as in n° 4.

When we pass to the category of connected K-schemes locally of finite type, [d1] equipped with a geometric point, over $\overline{K}/K$ (i.e. with an $x \in X$, [d2] a separable closure $\overline{k(x)}$ of $k(x)$ and a K-morphism $\overline{K} \hookrightarrow \overline{k(x)}$), this corresponds to a functor from K-schemes locally of finite type and connected, pointed over $\overline{K}/K$ (in the preceding sense) to the category of [d3] profinite groups [d4] π equipped with a homomorphism (of profinite groups)

$$\pi \longrightarrow \Gamma$$

fully faithful functor.

We must all the same make explicit the morphisms $(X, \xi) \longrightarrow (X', \xi')$ in the source category: morphisms of K-schemes $X \xrightarrow{f} X'$, equipped with a morphism of $\Pi_1(X')$[i1] (or|in class of paths) [d1] $f(\xi) \simeq \xi'$.

These conjectures reduce to Galois theory, for X of dimension 0. For X of dimension 1, they concern only X such that the connected components of $X_{\overline{K}}$ are of genus ≥ 2 (or, what comes to the same thing, introducing the finite extension $K' = H^0(X, \underline{O}_X)$ of K, so that X is geometrically connected over K', such that X as an algebraic [d2] curve[i2] over K' is of genus ≥ 2. We see easily (taking $X' = \mathrm{Spec}(K)$, X [d3] $= \mathbf{P}^1_K | \mathbb{P}^1_K$ or an elliptic curve over K) that they become false otherwise — 23

this is why it was necessary to introduce S, plus the anabelian hypothesis on (X, S),[i1] in order to associate to (X, S) a richer structure than $\Pi_1(X)$ over $\Pi_1(K)$. We shall find conjectures (for example)[i2] for X [d1] a geometrically connected curve over K of genus [d2]1 (resp. [d3]0), provided that S [d4] is of degree ≥ 1 (resp. ≥ 3)[i3].

6. Local analysis of (X, S) at an $s \in S$.

We are interested in the case where $\dim_s(X) = 1$, i.e. where s is not an isolated point of X.

Let O_s be the henselization (or the[i4] completion, if we insist) of $\underline{O}_{X,s}$, K_s its field of fractions, D_s^*= Spec(K_s), — we identify s with Spec $k(s)$ ($k(s)$ is the residue field of the gauge ring O_s). Let us consider $D_s = \text{Spec}(O_s)$, — ("arithmetic disk relative to|: $k(s)$"), thus $D_s^* = D_s \setminus \{s\} =$[i5] ("punctured disk") $\longrightarrow D_s$, 24

[scan 28]

[p. 12]

Let us now set

$$D_S = \coprod_{s\in S} D_s \qquad (\text{“arithmetic multidisk at } S\text{”})$$

$$D_S^* = \coprod_{s\in S} D_s^* \qquad (\text{“arithmetic multiannulus at } S\text{”})$$

We have a homomorphism of groupoids

$$\Pi_1(D_S^*) \xrightarrow{\sigma_S} \Pi_1(S) \quad (\xrightarrow{j_S} \Pi_1(K))$$

and a canonical isomorphism

$$\pi_1(\Pi_1(D_S)/\Pi_1(S)) \simeq j_S^*(\mathcal{T}(K))$$

With this set up, we also have a morphism

$$D_S^* \xrightarrow{\rho_S} X \setminus S$$

inducing

$$\Pi_1(D_S^*) \xrightarrow{\rho_S} \Pi_1(X \setminus S).$$

7. Thus, to (X, S) as in 5.1, we associate:

satisfying [d1] four compatibility conditions with α_{D^*D} and α'_{D^*D}, with α_{D^*U} and α'_{D^*U}, with α_{Ue} and $\alpha'_{U,e}$, with $\alpha_{D,e}$ and $\alpha'_{D,e}$ respectively. (i.e. we are working in a full subcategory of the 2-category of the Hom between fibered categories over Q, with fiber at e fixed…). I have the impression that this groupoid $\underline{\mathrm{Hom}}((f', \alpha'), (f, \alpha))$ is always rigid, i.e. $\mathrm{Aut}(f, \alpha)$ is always reduced to the trivial group — I'm too lazy to check — hence that if (f', α') and (f, α) are isomorphic, the isomorphism in question is unique. At any rate, we shall put

$\mathrm{Hom}((f', \alpha'), (f, \alpha)) = \pi_0 \underline{\mathrm{Hom}}((f', \alpha'), (f, \alpha))$

Whence a category of [d2] systems $(\Pi_U, \Pi_D, \Pi_{D^*}, \varphi, \psi, \rho, \sigma, \alpha, k)$

[scan 39]
d1

Thus, we have a relatively simple description of the "reduced" messy systems (i.e. where in the groupoids Π_U, Π_{D^*}, Π_D, each connected component has exactly one object, and where moreover[i1] we force in some sense $\Pi_1(K)|\Pi_e(K)$ to have only the object $\mathrm{Spec}(\overline{K})$. But we are found again on turning for|by the determination of the morphisms of the systems

$$\mathcal{G} = (I, G_i, p_i, k_i, \mathcal{E}, \varphi, \rho_i, \gamma_i) \quad \text{and} \quad \mathcal{G}' = (I', G'_{i'}, ...),$$

(or p?)[i3] [d2] say in the direction[i4]

$$f : \mathcal{G}' \to \mathcal{G}.$$

We therefore need (for f_{D^*})[i5] a map

$$\boxed{\tau = \tau_f : I' \to I},$$

and $\forall i'|i$ a homomorphism

$$\boxed{G'_{i'} \xrightarrow{f_{i'}} G_{\tau i'}},$$

[d4] (taking f_D into account)[i6] inducing by passage to the[i7] quotient homomorphisms

$$\Gamma'_{i'} \xrightarrow{g_{i'}} \Gamma_{\tau i'}$$

d5

m118

Marginal note. [m118] The "simplified messy objects" are thus the systems of homomorphisms of exact sequences

$$\begin{array}{ccccccc} 1 & \longrightarrow & T(\overline{K}) & \xrightarrow{k_i} & \mathcal{E}_i & \xrightarrow{p_i} & \Gamma \\ & & \downarrow{\scriptstyle \rho_i^0} & & \downarrow{\scriptstyle \rho_i} & & \downarrow{\scriptstyle \mathrm{int}(\gamma_i)} \\ 1 & \longrightarrow & \pi|\Pi & \xrightarrow{\kappa} & \mathcal{E} & \xrightarrow{p} & \Gamma \end{array}$$

[scan 41]

datum of the commutativities α_{D^*U}, and write the compatibility conditions with α, α' and k, k'. The datum of $\alpha_{D^*,U}$ is equivalent to that of systems of elements

$$\boxed{\beta_{i'} \in \mathcal{E}'} \qquad (i' \in I')$$

[d1]such that[i1] one has, in the diagrams

$$\begin{array}{ccc} G'_{i'} & \xrightarrow{\rho'_{i'}} & \mathcal{E}' \\ {\scriptstyle f_{i'}}\downarrow & & \downarrow{\scriptstyle f_{\mathcal{E}}} \\ G_{\tau i'} & \xrightarrow[\rho_{\tau i'}]{} & \mathcal{E} \end{array}$$

the relation

$$f_{\mathcal{E}} \rho'_{i'} = \mathrm{int}(\beta_{i'}) \rho_{\tau i'} \circ f_{i'}.$$

It remains to express the two[i2] compatibilities [d2] of $(f_{D^*}, f_D, f_U, \alpha_{D^*D}, \alpha_{De}, \alpha_{D^*U}, \alpha_{Ue})$ with itself and with K — the second compatibility is simply the compatibility of the $f_{i'}$ with the $k'_{i'}, k_i$, i.e.

$$f_{i'} \circ k'_{i'} = k_i \qquad (i = \tau i')$$

and the first unless I am mistaken is expressed by the "commutativity"

$$\alpha \gamma'_{i'} = \rho(\beta_{i'}) | p(\beta_{i'}) \gamma_i \alpha_{i'} \qquad \forall i' \in I'$$

$$\boxed{\alpha_{i'} = \gamma_i^{-1} \rho | p(\beta_{i'}^{-1}) \alpha \gamma'_{i'}}$$

[scan 44]

[p. 20]

A homomorphism from a system $(\mathcal{E}', p', (\mathcal{E}'_{i'})_{i' \in I'}, (k'_{i'})_{i' \in I'})$ into a system $(\mathcal{E}, p, (\mathcal{E}_i)_{i \in I}, (k_i)_{i \in I})$ is given by by a homomorphism

$$f : \mathcal{E}' \longrightarrow \mathcal{E}$$

$$\beta_{i'} \in \mathcal{E} \quad (i' \in I'), \qquad \alpha \in \Gamma,$$

such that one has the conditions:

m124

Marginal note. m124 The $\beta_{i'}$ not unique (if $\beta_{i'}$ works, also $\gamma\beta_{i'}$, with $\gamma|\gamma_i \in \operatorname{Im} k_i$). But α unique ?!|??

1°) $p \circ f_{\mathcal{E}} = \operatorname{int}(\alpha)\, p'$

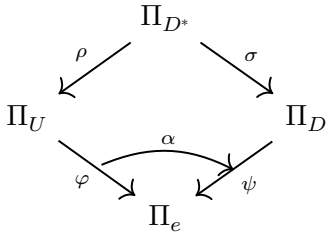
2°) $\forall i' \in I', \quad \exists i \in I$ (unique!) such that

$$\operatorname{int}(\beta_{i'}^{-1}) f(\mathcal{E}'_{i'}) \subset \mathcal{E}_i$$

and an integer $d_{i'} \in \mathbb{N}^*$ such that

$$\operatorname{int}(\beta_{i'}^{-1}) f k'_{i'} = k_i \circ (d_{i'} \cdot \mathrm{id}_{T(\bar{K})})$$

N.B.: $d_{i'}$ is also unique…



m126

Marginal note. m126 [thus $\operatorname{int}(\beta_{i'}^{-1})\overbrace{\operatorname{Im}(f k'_{i'})|\operatorname{Im} k'_{i'}}^{L'_{i'}} \subset \underbrace{\operatorname{Im} k_i}_{L_i}$ and even d1 $\operatorname{int}(\beta_{i'}^{-1}) L'_{i'} = d_{i'} L_i$.]

I realize that it is better to replace the $\beta_{i'}$ by the $\beta_{i'}^{-1}$, i.e. to take the commutation isomorphism rather in the direction

$$f_{\mathcal{E}} \rho'_{i'} \xrightarrow{\beta_{i'}} \rho_i f_{i'}$$

than in the opposite direction. Moreover, conceptually the diagram

is too complicated, it suffices to give oneself

$$\boxed{\Pi_{D^*} \xrightarrow{\rho} \Pi_U \xrightarrow{\varphi} \Pi_e}$$

and to deduce Π_D by canonical factorization

43

d1 (two compatibility conditions on the two squares).

If we d2 restrict ourselves to connected Π_U, Π'_U, we find by choosing as above an object $\widetilde{U}$i1 of Π_U and an isomorphism

$$\boxed{\varphi(\widetilde{U}) \overset{\lambda}{\simeq} \Omega}$$

(where $\Omega = \mathrm{Spec}(\bar{K})$ is the reference object of Π_e ...), a group $\mathcal{E}$ and a homomorphism

$$\mathcal{E} \overset{\varphi}{\to} \Gamma$$

(which is changed by an inner automorphism if we change λ, and $\mathcal{E}$ itself replaced by an isomorphic group, with isomorphism defined modulo inner isomorphisms, if we change the reference object $\widetilde{U}$). Likewise, choosing a $\widetilde{U}_i$ in each component $i \in \pi_0(\Pi_{D^*})$, and isomorphisms

$$\lambda_i : \rho(\widetilde{U}_i) \simeq \widetilde{U},$$

we find groups $\mathcal{E}_i$ and homomorphisms

$$\mathcal{E}_i \overset{\rho_i}{\to} \mathcal{E}.$$

If we change λ_i, ρ_i is changed by an inner automorphism of $\mathcal{E}$. If we change $\widetilde{U}_i$, $\mathcal{E}_i$ is replaced by an isomorphic group, the isomorphismi2 defined up to an inner automorphism. 45

Let us consider the composites

$$\mathcal{E}_i \longrightarrow \mathcal{E} \xrightarrow[p]{} \Gamma \qquad \mathcal{E}_i \xrightarrow{p_i} \Gamma$$

whence kernel, [d1] $K|k$ is defined by a system of isomorphisms

$$T(\bar{K}) \overset{k_i}{\simeq} \operatorname{Ker} p_i \qquad (i \in I)$$

fitting into a family of exact sequences

$$1 \longrightarrow T(\bar{K}) \xrightarrow{k_i} \mathcal{E}_i \xrightarrow{p_i} \Gamma$$

(N.B. the image of p_i is an open subgroup) k_i being compatible with the actions of $\mathcal{E}_i$, when we let $\mathcal{E}_i$ act on $T(\bar{K})$ through the action of Γ on $T(\bar{K})$, and on itself by inner automorphisms. Introducing also $\pi = \operatorname{Ker} p$, we thus find homomorphisms of exact sequences

$$(D) \qquad \begin{array}{ccccccc} 1 & \longrightarrow & T(\bar{K}) & \xrightarrow{k_i} & \mathcal{E}_i & \xrightarrow{p_i} & \Gamma \\ & & \downarrow{\scriptstyle \varepsilon_i} & & \downarrow{\scriptstyle \rho_i} & & \| \\ 1 & \longrightarrow & \pi & \xrightarrow[k|\kappa]{} & \mathcal{E} & \xrightarrow[p]{} & \Gamma \end{array} \qquad i \in I$$

[d3] We can say that Π_U defines an "outer group" $[\mathcal{E}]$, and $\Pi_U \longrightarrow \Pi_e$ a homomorphism of outer groups

$$[\mathcal{E}] \longrightarrow [\Gamma],$$

likewise Π_{D^*} defines a system of "outer groups" $[\mathcal{E}_i]$, and [d4] $\Pi_{D^*} \longrightarrow \Pi_U$ 46

[scan 52]

[p. 24]

Note that, since ρ_i is injective, the second relations, giving the $\rho_i(\mu_{i'})$, determine the $\mu_{i'}$ in a unique way, the existence of these $\mu_{i'}$ is equivalent to the relations

$$\boxed{\alpha'_{i'}\alpha_{i'}^{-1} \in \rho_i(\mathcal{E}_i)} \qquad i' \in I'.$$

As for the relation $p(\mu) = \alpha'\alpha^{-1}$, it determines μ modulo multiplication (on the right, say)[i1] by a [d1] $\mu_0 \in \mathrm{Ker}\, p = \pi$, but which must be such that we still have

$$f'_{\mathcal{E}} = \mathrm{int}(\mu\mu_0) f_{\mathcal{E}}$$

(in addition to $f'_{\mathcal{E}} = \mathrm{int}(\mu) f_{\mathcal{E}}$) which means [d3] that

$$\mathrm{int}(\mu_0) f_{\mathcal{E}} = f_{\mathcal{E}} | f'_{\mathcal{E}}$$

i.e.

$$\boxed{\mu_0 \in \mathrm{Centr}_{\pi} f_{\mathcal{E}}(\mathcal{E}')}$$

So that is the exact indeterminacy in the choice of a 0-morphism the|of the 1-morphisms [d5] f and f' from $\mathcal{D}'$ to $\mathcal{D}$. If for example we are under the conditions where $\pi' \longrightarrow \pi$ induced by $f_{\mathcal{E}} : \mathcal{E}' \longrightarrow \mathcal{E}$ [d6] has an image of finite index (open image) — case of a "nonconstant morphism"! — then μ_0 must centralize an open subgroup of

[p. 25]

N.B. The $i \in I$ corresponding to $i' \in I'$ is unique, whence $\tau : I' \longrightarrow I$. If the $\alpha_{i'}$ are chosen, we deduce [d1] induced homomorphisms $f_{i'} : \mathcal{E}'_{i'} \longrightarrow \mathcal{E}_i$,

$$f_{i'} = (\mathrm{int}(\alpha_{i'}) \circ f)|\mathcal{E}'_{i'},$$

which then induces, via the $k'_{i'}, k_i$, an endomorphism

$$f^0_{i'} : \mathrm{T}(\overline{K}) \longrightarrow \mathrm{T}(\overline{K}).$$

m148

Marginal note. [m148] N.B. A priori $f^0_{i'}$ is multiplication by $\chi_{i'} \in \widehat{\mathbb{Z}}^*|\widehat{\mathbb{Z}}$. The centralizer in Γ of an open subgroup is reduced to the identity.

We require that $\alpha \in \Gamma$ (which conjugates $f_{\mathcal{E}}$ to $f'_{\mathcal{E}}$}, and is probably uniquely determined by this condition) and $\alpha_{i'}$ (which is probably determined modulo [d2] composition on the left with an element of the normalizers|of the normalizer of $\mathcal{E}_i$ (at least of the transporters of the $\mathcal{E}_i$[i1] of an open subgroup of $\mathcal{E}_i$ — it is the same if f is an isomorphism) can be chosen in such a way that, putting

$$\beta_{i'} = p(\alpha_{i'})\alpha,$$

we have

$$f^0_{i'} = (d_{i'}\chi(\beta_{i'}))\,\mathrm{id}_{\mathrm{T}(\overline{K})}$$

i.e. $\chi_{i'} = d_{i'}\chi(\beta_{i'})$[i2] m149

Marginal note. [m149] This condition on the systems of the $\alpha_{i'}$ does not change (α remaining fixed) if we change $\alpha_{i'}$ to $\mu_{i'}\alpha_{i'}$, where $\mu_{i'} \in \mathcal{E}_i$.

$d_{i'} \in \mathbb{N}^*$ is a natural integer obviously uniquely determined } when α and the $\alpha_{i'}$ are chosen). [d3]

8, Taxonomic reflection.

The case $\dim X = 0$ translates in the paradigm of the system $(\mathrm{T}(\overline{K}) \overset{k_i}{\longrightarrow} \mathcal{E}_i \overset{\rho_i}{\hookrightarrow} \mathcal{E} \overset{p}{\to} \Gamma)$ [d1] into the condition [d2] p injective, [d3] and thus $I = \emptyset$ — so this case is[i1] described [d4] simply by giving an open subgroup $\mathcal{E} \subset \Gamma$, i.e. a finite subextension L of $\overline{K}/K$ (N.B. of course we will have $X' = \mathrm{Spec}\, L'|L$, and the choices made[i2] on X — i.e. on $\Pi_{\mathcal{D}^*} \longrightarrow \Pi_U \longrightarrow \Pi_e$ —[i3] leading|lead to this description — amount here to the choice of such a $\underset{=\emptyset}{K}$-[i4]embedding of $L = \mathrm{H}^0(X, \mathcal{O}_X)$ into $\overline{K}/K$)

The case $\dim X = 1$ translates into the fact that $\mathcal{E} \longrightarrow \Gamma$ is not injective — as for I, it may be empty or not in this case. If it is empty, the description is thus simply in terms of a homomorphism of profinite groups $\mathcal{E} \overset{p}{\to} \Gamma$ (where Γ given in advance $= \mathrm{Gal}(\overline{K}/K)$ $\} = \mathrm{Aut}_{\Pi_e}(\Omega)$).

Suppose now given both

$$\mathcal{D} = (\mathcal{E}, p, I, (\rho_i : \mathcal{E}_i \hookrightarrow \mathcal{E}), (k_i : \mathrm{T}(\overline{K}) \longrightarrow \mathcal{E}_i))$$

and

$$\mathcal{D}' = (\mathcal{E}', p', I', (\rho'_{i'} :), (k'_{i'} :)),$$

and let us return to the question of the description of the morphisms from $\mathcal{D}'$ to $\mathcal{D}$. We are going to distinguish four cases, according to the two values 54

$0, 1$ possible for $n = \dim \mathcal{D}$ and $n' = \dim \mathcal{D}'$ respectively.

I) $n = 0, n' = 0$, [d1] $I = I' = \emptyset$ and the data reduce to open subgroups $\mathcal{E} \overset{p}{\hookrightarrow} \Gamma$, $\mathcal{E}' \overset{p'}{\hookrightarrow} \Gamma$. In the cumbersome description above, [d2] the considerations relating to I, I' drop out and the (a) morphism $\mathcal{D}' \longrightarrow \mathcal{D}$ amounts to a class of [d3] pairs (f, α), where $f : \mathcal{E}' \longrightarrow \mathcal{E}$ and $\alpha \in \Gamma$, such that we have

$$pf = \mathrm{int}(\alpha) f$$

— which implies that f is already determined by α, being induced by $\mathrm{int}(\alpha)$ [α subject to $\alpha \in \mathrm{Trans}_\Gamma(\mathcal{E}', \mathcal{E}) = \mathrm{Trans}_\Gamma(L, L')$][i1] [d4]

$$\begin{array}{ccc} \mathcal{E}' & \xrightarrow{f} & \mathcal{E} \\ {\scriptstyle p'}\downarrow & & \downarrow{\scriptstyle p} \\ \Gamma & \xrightarrow[\sim]{\mathrm{int}(\alpha)} & \Gamma \end{array}$$

[which induces thus|indeed a homomorphism from $L^*|L \subset \overline{K}$ to $L' \subset \overline{K}$, hence a homomorphism $\mathrm{Spec}(L') \longrightarrow \mathrm{Spec}(L)$ in the opposite direction].

The condition that $\alpha, \alpha' \in \Gamma$ define the same morphism $\mathcal{D}' \longrightarrow \mathcal{D}$ (or again $\mathrm{Spec}\, L' \longrightarrow \mathrm{Spec}\, L$) is described by the existence of a $\mu \in \mathcal{E}$ [d5] such that $\alpha' = \mu\alpha$. The fact that we give a 1-1 correspondence between

$$\mathrm{Hom}_K(X', X) \simeq \mathrm{Hom}_K(L, L')$$

with $\mathrm{Hom}(\mathcal{D}', \mathcal{D})$ made explicit too, is clear. 55

II) $n' = 1, n = 0$. Here $n = 0$ already implies $I = \emptyset$.[i1] [d1] For $\mathrm{Hom}(X', X) \neq \emptyset$, we must have $I' = \emptyset$ [by the condition $f^{-1}(S) = S'$ which implies $S' = \emptyset$, if $f : (X', S') \longrightarrow (X, S)$]

$f^{-1}(\emptyset) = \emptyset$[i2] — [d2] in the description of the morphisms $\mathcal{D}' \longrightarrow \mathcal{D}$, this corresponds to the fact that we can have a map $\tau : I' \longrightarrow I(= \emptyset)$ only if $I' = \emptyset$. [d3] Restricting ourselves therefore to the case $I' = \emptyset$ (otherwise $\mathrm{Hom}(X', X) = \mathrm{Hom}(\mathcal{D}', \mathcal{D}) = \emptyset$ and we are happy), we thus find that $\mathcal{D}$ amounts to giving $\mathcal{E} \overset{p}{\hookrightarrow} \Gamma$ an open subgroup, and $\mathcal{D}'$ to giving a homomorphism of profinite groups $p' : \mathcal{E}' \longrightarrow \Gamma$, whose image will be an open subgroup of Γ, say $\Gamma'_0 \subset \Gamma$, corresponding to a finite[i3] subextension L' of $\overline{K}/K$. [m155]

this we cannot

Marginal note. [m155] Restricting ourselves therefore to the case

The choices made concerning X' imply precisely|that we have a fixed isomorphism $L' \simeq \mathrm{H}^0(X', \mathcal{O}_{X'})$. That said, a K-morphism from $(X', \emptyset)$ to $(X, \emptyset)$ i.e. from[i4] $X' \longrightarrow X$ amounts (since X affine)[i5] to giving a K-morphism $\mathrm{Spec}\, L' \longrightarrow X$ ($\simeq \mathrm{Spec}\, L$) from the affine envelope, i.e. a K-[i6]homomorphism $L \longrightarrow L'$. (which depends only on L, L', or again on the [d4] subgroups $\mathcal{E} \subset \Gamma$ and $\Gamma_0 \subset \Gamma$ 56

[p. 27]

of Γ). On the other hand the description in terms of the diagrams $\mathcal{D}, \mathcal{D}'$ amounts to saying that a morphism is determined by a pair (f, α), $f : \mathcal{E}' \longrightarrow \mathcal{E}$ and $\alpha \in \Gamma$, such that we again have commutativity

$$\begin{array}{ccc} \mathcal{E}' & \xrightarrow{f} & \mathcal{E} \\ {\scriptstyle p'}\downarrow & & \downarrow{\scriptstyle p} \\ \Gamma & \xrightarrow{\mathrm{int}(\alpha)} & \Gamma \end{array}$$

$$pf = \mathrm{int}(\alpha)p'$$

which again implies that f is determined by α (namely, induced by $\mathrm{int}(\alpha)$), and α being subject to the sole condition

$$\alpha \in \mathrm{Transp}_\Gamma(\Gamma'_0, \mathcal{E})$$

— and α, α' describing|describe the $=$ homomorphism iff

$$\exists \mu \in \mathcal{E} \quad \text{such that} \qquad \Longleftarrow \mid \Longleftrightarrow$$

$$\alpha' = \mu\alpha$$

so we again have

$$\begin{aligned} \mathrm{Hom}(\mathcal{D}', \mathcal{D}) &\simeq \mathcal{E} \backslash \mathrm{Transp}_\Gamma(\Gamma'_0, \Gamma) \\ &\simeq \mathrm{Transp}_\Gamma(L, L') / \mathrm{Fix}_\Gamma(L) \\ &\simeq \mathrm{Hom}_{K\text{-ext}|K\text{-cat}}(L, L') \end{aligned}$$

so we again find in this case the|the full faithfulness.

In fact, we could have treated together 57

[scan 60]

[p. 28]

common description given in I, II, without any other hypothesis on X than [d1] 0-connectedness (to be able to describe $\Pi_U = \Pi_{X'}$ over Π_e in terms of a group homomorphism $p' : \mathcal{E}' \longrightarrow \Gamma$ ...).

When we are given (X', S'), with S' not necessarily empty, X' 0-connected (and [d2] X' smooth of dimension 1 at the points of S' (it would suffice = that S' not disconnect|disconnect locally (étale)[i1] X', ...), thus $X' - S'$ 0-connected[i2] then the [d3] datum $\Pi_1(X' - S') \longrightarrow \Pi_1(e_K)$ is described [d4] by $\mathcal{E}' \xrightarrow{p'} \Gamma$ (independently of the consideration of the $\mathcal{E}_i$ etc) and hence $\mathrm{Hom}_K(X' - S', X)$ is described as we just said. But we have (with the normality hypotheses on X' at the points of S')

$$\mathrm{Hom}_K(X' - S', X) = \mathrm{Hom}_K(X', X).$$

This encourages modifying the definition of morphisms $(X', S') \longrightarrow (X, S)$ given at the|by beginning, via $f : X' \longrightarrow X$ with $f^{-1}(S)_{\text{réd}} = S'$, by requiring this not for f, but[i3] only for the restriction of f to the union of the irreducible components of X' 59

Scans 61–70

[scan 61]

d1 which are sent into irreducible components of X d2 that are non-discrete i.e. not reduced to a point. In the corresponding description $\mathcal{D}' \to \mathcal{D}$, we specified that one requires the datum of a map $I' \to I$ (and of the corresponding data $f_{i'}, \alpha_{i'}$) only if d3 $n \neq 0$ i.e. $p_{si}|p_X \colon \mathcal{E} \to \Gamma$ not injective, — in the contrary case (implying $I = \emptyset$) if by chance $I' \neq \emptyset$,i1 one drops the knowledge of I' and of the corresponding structure elements.

III) $n' = 0$, $n = 1$. Here one thus has $I' = \emptyset$, $p' : \mathcal{E}' \hookrightarrow \Gamma$ i.e. $\mathcal{D}'$ reduces to the datum of an open subgroup $\mathcal{E}' \hookrightarrow \Gamma$ of Γ. On the side of $(X', S' = \emptyset)$ and (X, S), the condition $f^{-1}(S)_{\text{réd}} = S' = \emptyset$ on the K-morphismi2 $f : X' \to X$ implies that f factors through $X' \Longrightarrow \mathrm{Spec}(L') \longrightarrow X \setminus S$, regardless of whether $S = \emptyset$ or not, i.e. whether $I = \emptyset$ or not. Thus it is a matter of describing $\mathrm{Hom}_{K\text{-sch}}(X', X \setminus S)$, in terms of $\begin{matrix} \Pi_{U'} \\ \| \\ \Pi_1(X') \end{matrix} \to \Pi_e = \Pi_1(e_K)$ 60

[p. 29]

and of $\begin{matrix} \Pi_U \\ \| \\ \Pi_1(X \setminus S) \end{matrix} \to \Pi_e$. Here the possible additional data relating to I do not serve explicitly in the description, in terms of diagrams (of groupoids)i2. Unless I am mistaken, an easy reduction (Galois descent)i3 brings us back to the case where $X' = \mathrm{Spec}\, K$ i.e. $\mathcal{E}' \Leftrightarrow \Gamma$. The description of the|in homomorphisms $\mathcal{D}' \to \mathcal{D}$ is then stilli4 in terms of pairs (f, α), where $f : \mathcal{E}' = \Gamma \to \mathcal{E}$ and where $\alpha \in \Gamma$, with the everlasting condition $pf = \mathrm{int}(\alpha)p'$, which becomes (as $p' = \mathrm{id}$)

$$pf = \mathrm{int}(\alpha).$$

d1 Here of course α no longer describes f (but the converse is d2 true, here knowledge of f hence of $pf \in \mathrm{Aut}(\Gamma)$ implies that of α, i.e. $\mathrm{Cent}(\Gamma) = \{1\}$ …). The pairs (f, α) and (f', α')

define the = morphism of diagrams, iff $\exists \mu \in \mathcal{E}$ such that $f' = \mathrm{int}(\mu) \circ f$, $\alpha' = p(\mu)\alpha$. As (if $\exists (f, \alpha)$) p is surjective, 61

[scan 63]

one sees|wants that, on choosing μ over d1 α^{-1}, and replacing (f, α) by $(f', \alpha') = (\mathrm{int}(\mu)f, p(\mu)\alpha)$, one can always describe a morphism $\mathcal{D}' \to \mathcal{D}$ by (f, α) with $\alpha = 1$ hence by a section f of the homomorphism $\mathcal{E} \to \Gamma$, and two sections f, f' (corresponding to $(f, 1), (f', 1)$) define the = homomorphism from $\mathcal{D}'$ to $\mathcal{D}$, iff $\exists \mu \in \mathcal{E}$ such that $p(\mu) = 1$ i.e. $\mu \in \pi = \mathrm{Ker}(p)$, and such that $f' = \mathrm{int}(\mu) \circ f$.

Thus, the morphisms from $\mathcal{D}'$ (corresponding to $X' = \mathrm{Spec}\, K$) to $\mathcal{D}$ correspond exactly to the classes of splittings of $\mathcal{E} \xrightarrow{p} \Gamma$, modulo inner automorphisms by $\mu \in \pi = \mathrm{Ker}\, p$. The "messy conjecture" in case III is thus equivalent to this: m162

Marginal note. m162

d2

$$\Gamma((X, S)/K) \longrightarrow \begin{array}{c} \pi\text{-conjugacy classes of} \\ \text{sections of } \mathcal{E} \to \Gamma \text{ i.e.} \\ \text{of sections of } \Pi_1(X) \to \Pi_1(e_K) \end{array}$$

is bijective (if (X, S) is an allowed "anabelian" pair). m164

Marginal note. m164 false as it stands, cf. number 9 below — one needs additional conditions on the f … Perhaps true if $I = \emptyset$

I know in any case that this map is injective — this holds whenever one has a scheme U over K (here $X \setminus S$) which embeds in an algebraic group G[i1] extension of an abelian variety by a torus, and then follows from the "absolute" Mordell-Weil theorem: $G(K)$ is a finitely generated $\mathbb{Z}$-module. In fact, it suffices to know the splitting class of the extension $\mathcal{E}^\natural$ of Γ by

$$\pi_{\text{ab}} = \pi/\overline{[\pi,\pi]} \simeq H_1(\text{Alb}|U),$$

d1 corresponding[i2] to a point of U rational/K, to know this point. Thus the result of[i3] faithfulness is obtained, with less draconian hypotheses on X than the anabelian hypothesis (with the notation of lemma 5.2, this means that $g = 0 \Rightarrow n|\nu \geq 2$ i.e. that there is no irreducible component of $X_{\overline{K}}|U_{\overline{K}}$ which is isomorphic to $\mathbb{P}^1_{\overline{K}}$ or $\mathbb{E}^1_{\overline{K}}$ …). 63

[p. 31]

the study of the|of the case $\overline{\text{II}}$) are moreover described in a "fully faithful" way by homomorphisms of diagrams — They correspond to the cases $f : \mathcal{E}' \to \mathcal{E}$ which are zero on π'.

b) The case $I' = \emptyset$, $I \neq \emptyset$ (i.e. $S' = \emptyset$, $S \neq \emptyset$) means, for the condition $f^{-1}(S)_{\text{réd}} = S'$ i.e. $f^{-1}(S) = \emptyset$, that f must map X' into $X \setminus S$, [d1] therefore that the f corresponding to a morphism from $(X', \emptyset)$ to (X, S) are constant. The messy conjecture in this case therefore expresses [d2] essentially that at the level of the homomorphisms $\mathcal{E}' \xrightarrow{p'} \Gamma$ and $\mathcal{E} \xrightarrow{p} \Gamma$, every group homomorphism $\mathcal{E}' \xrightarrow{f} \mathcal{E}$ such that $pf = \text{int}(\alpha)p'$ for $\alpha \in \Gamma$ [one is reduced to the case where $\alpha = 1$, p, p' surjective[i1] i.e. to homomorphisms of extensions of Γ by the|some groups $\pi = \pi_1(\overline{X \setminus S})$ and $\pi' = \pi_1(\overline{X}')$)] is trivial on π' [i.e. "is" a section]. One should try to verify this point directly, which (modulo case $\overline{\text{III}}$) would establish the "messy conjecture" in that case. 65

[scan 68]

[p. 32]

seem far, = if K finite over $\mathbb{Q}$ …)

Elementary reductions To prove the "messy conjecture", one is reduced (by finite extensions of the fields K) to the case where $\mathcal{E} \to \Gamma$ (and, if one insists, also $\mathcal{E}' \to \Gamma$) is an epimorphism. Unless I am mistaken, knowledge of case Ш for finitely generated extensions of K, implies the general case for K (with enough technical sweat …).

Returning however to the general case when $\mathcal{E} \to \Gamma$ is surjective, in every equivalence class of systems $(f : \mathcal{E}' \to \mathcal{E}, \alpha \in \Gamma,$ d2 $\tau : I' \to I,$ d3 $(\alpha_{i'} \in \mathcal{E}_{\tau(i')=i})_{i' \in I'})$, one can find a system with $\alpha = 1$, so that $f : \mathcal{E}' \to \mathcal{E}$ is compatible with the homomorphisms to Γ (i.e. the extension structures). When one restricts oneself to such systems, the|their equivalence by conjugation is effected by a system $(\mu, (\mu_{i'})_{i' \in I'})$ with $\mu \in \pi$ $(= \operatorname{Ker} p)$, and 67

the $\mu_{i'} \in \mathcal{E}_{i=\tau(i')}$ as before. Thus, $f : \mathcal{E}' \to \mathcal{E}$ is d1 a[i1] homomorphism of extensions, defined modulo inner automorphisms by an element of $\pi = \operatorname{Ker}(\mathcal{E} \to \Gamma)$, and satisfying conditions made explicit elsewhere. It could be (as we have already remarked) that knowledge of the d2 π-conjugacy class of f suffices to determine the "messy morphism" into which f fits (if $I, I' \neq \emptyset$).

[This is linked to the question of whether the d3 d4 $\forall d \in \mathbb{N}^*$, $\operatorname{Trans}_{\mathcal{E}}(L_i^d, L_i)$ is reduced to $\mathcal{E}_i$ (where $L_i = \operatorname{Ker}(p_i : \mathcal{E}_i \to \Gamma) = \operatorname{Im}(\kappa_i : T(\overline{K}) \to \mathcal{E}_i)$). In that case, $\mathcal{E}_i$ would be known in terms of $L_i \subset \pi$, and = in terms of the rays|kernels of subgroups that it defines in π, and a fortiori in terms of the rays|kernels of homomorphisms defined by $\kappa_i : T(\overline{K}) \to \pi$ …. 68

[p. 33]

Case where the[i1] $\mathcal{E}_i \to \Gamma$ [d1] surjective (i.e. the[i2] $k(s_i) = K$ i.e. s_i rational over K). Then, if $(f,$ [d2] $\tau,$ [d3] $(\alpha_{i'}))$ is a homomorphism from $\mathcal{D}'$ to $\mathcal{D}$, [d4] after [d5] correcting[i3] by $\mu_i \in \mathcal{E}_i$ having the $=$ image as the $\alpha_{i'}$ in Γ, one may assume $\alpha_{i'} \in \pi$, in addition to $\alpha = 1$ (obtained by correcting by a suitable μ). Thus one describes the homomorphism $\mathcal{D}' \to \mathcal{D}$[i4] by $(f, 1, \tau, (\alpha_{i'}))$, the $\alpha_{i'} \in \pi$. The [d6] condition[i5] [d7] here is that $f : \mathcal{E}' \to \mathcal{E}$ be a group homomorphism over Γ, that [d8] $f(\mathcal{E}'_{i'}) \subset \mathrm{int}(\alpha_{i'}^{-1})(\mathcal{E}_{\tau(i')=i})$, and that the homomorphism induced $\mathcal{E}'_{i'} \to \mathcal{E}_i$[i8] by [d9] $\mathrm{int}(\alpha_{i'})f|\mathrm{int}(\alpha_{i'}^{-1})f$ [d10] induces on $T(\overline{K})$ (via $\kappa_{i'}, \kappa_i$) the homomorphism of multiplication by d_i and nothing more — how beautiful! Two systems $(f, \tau, (\alpha_{i'}))$ and $(f', \tau', (\alpha'_{i'}))$ define the $=$ morphism, iff $\tau = \tau'$ and if there[i9] exists

$$\mu \in \pi, \quad \mu_{i'} \in \begin{matrix} L_{i=\tau(i')} \\ \| \\ \kappa_i(T(\overline{K})) \end{matrix}$$

such that

$$f' = \mathrm{int}(\mu) f$$

$$\alpha'_{i'} = \mu_{i'} \alpha_{i'}.$$

[d11] Let us note that a priori, for (f, τ) fixed, the $\alpha_{i'}$ are determined modulo right multiplication by elements of $\mathrm{Transp}_\pi((L_i^{d_{i'}}, L_i)$, 69

which is probably $= L_i = \mathrm{Ker}(p_i : \mathcal{E}_i \to \Gamma) = 1|$the $\mathrm{Im}(\kappa_i : T(\overline{K}) \to \mathcal{E}_i \cap \pi)$. Thus we find that [d1] the [d2] π-conjugacy class of groups over Γ of $f : \mathcal{E}' \to \mathcal{E}$ suffices to determine the homomorphism $\mathcal{D}' \to \mathcal{D}$ in the messy category. I presume that a little sweat would make it possible to prove that this still works in the general case (without assuming the $\Gamma_i = \mathrm{Im}(\mathcal{E}_i \to \Gamma)$ equal to Γ). This means (in the present case) that the essential structure which describes (X, S) is that of an [d3] "outer extension" of Γ by a group π [surjective outer homomorphism from a group, with kernel a π], with π equipped with a loop structure i.e. [d4] of homomorphisms[i1] outer

$$\kappa_i : T\dagger|\mu\,(= T(\overline{K})\,\dagger \overset{\text{noncanonically}^t}{\simeq} \widehat{\mathbf{Z}}) \to \pi$$

(satisfying certain conditions), the 70

homomorphisms from[i1] $\mathcal{E}' \to \Gamma$ (kernel π') into $\mathcal{E} \to \Gamma$ (kernel π) being the π-conjugacy classes of homomorphisms $\mathcal{E}' \to \mathcal{E}$ of groups over Γ, inducing homomorphisms $\pi' \to \pi$ compatible with the loop structure.

9. Tangential structure at the $s \in S$. [m175]

Marginal note. [m175] [The sections of extensions "of the second type"]

Returning to the "intrinsic"[i2] description of the (X, S) by $\Pi_{D^*} \to \Pi_U \to \Pi_e$, an $s_i \in S$ thus corresponds to a connected component $\Pi_{D_i^*}$[i3] of Π_{D^*}, or a Π_{D_i}[i4] of its quotient Π_D — consider

$$\Pi_{D_i^*} \xrightarrow{\sigma_i = \Pi_{f_{D_i^* D_i}} | \sigma_i = \sigma_{D_i^* D_i}} \Pi_{D_i}.$$

We are going to describe certain sections (up to isomorphism) of this [d1] morphism[i5] of groupoids, i.e. pairs (γ, λ)[i6] functors $\Pi_{D_i} \xrightarrow{\gamma} \Pi_{D_i^*}$ and an isomorphism $\sigma_i \circ \gamma \overset{\lambda}{\simeq} \mathrm{id}$. If we choose a $\widetilde{D}_i^* \in \mathrm{Ob}\,\Pi_{D_i^*}$ (universal covering of D_i^*), whence a surjective[i7] homomorphism

$$\mathcal{E}_i = \mathrm{Aut}(\widetilde{D}_i^*) \to \Gamma_i = \mathrm{Aut}(\sigma_i(\widetilde{D}_i^*) = \widetilde{D}_i),$$

the [d2] datum of $(\gamma, \lambda_i|\lambda)$, and of an isomorphism $\gamma(\widetilde{D}_i) \simeq \widetilde{D}_i^*$ giving the identity isomorphism on applying the σ_i,[i8] amounts to that of a homomorphism $\Gamma_i \to \mathcal{E}_i$. — and the isomorphism classes of the pairs (γ, λ) correspond to the L_i[i9]-conjugacy classes 71

$(L_i = \mathrm{Ker}(\mathcal{E}_i \to \Gamma_i))$ of [d2] sections[i2] of the extension $\mathcal{E}_i$ of Γ_i by L_i.

This being so, we have

$$\Gamma_i = \mathrm{Gal}(\overline{K}_i/K_i).$$

where $K_i = k(s_i)$, $\overline{K}_i$ is the algebraic closure of K_i defined by $\widetilde{D}_i$ (a priori, it is not canonical[ly] isomorphic to $\overline{K}$ over K…), and the classes of [d3] splittings[i3] of extensions form a torsor Σ_i[i4] (if

there are any, and we know that there are…) under $H^1(\Gamma_i, L_i)$, or again, since $\kappa_i : L_i \overset{\sim}{\leftarrow} T(\overline{K}_i)$, under

$$H^1(\mathrm{Gal}(\overline{K}_i/K_i), T(\overline{K}_i)) \simeq H^1(K_i, T_e|T_\ell(G_m)) \simeq \varprojlim_n H^1(K_i, \mu_n).$$

Now the Kummer exact sequence gives

$$\begin{array}{ccccccccc} 0 & \to & H^0(K_i,\, G_m)_n & \to & H^1(K_i, \mu_n) & \to & {}_nH^1(K_i, G_m) & \to & 0 \\ & & \| & & & & \| & & \\ & & (K_i^*)_n & & & & 0 & & \end{array}$$

i.e. $H^1(K_i, \mu_n) \simeq (K_i^*)_n$, hence

$$H^1(K_i, T(G_m)) \simeq \varprojlim_n (K_i^*)_n$$

[p. 35]

Note that we have a Kummer homomorphism

$$K_i^* \to \underbrace{H^1(K_i, T(G_m))}_{\mathcal{H}_i} \simeq \varprojlim (K_i^* n)$$

whose kernel consists of the $x \in K_i^*$ such that for $\forall\ n \in \mathbf{N}$, we have $x \in K_i^{*n}$. Since K_i is of finite type over $\mathbf{Q}$, this homomorphism is injective, i.e. K_i^* is identified with a subgroup of $\mathcal{H}_i$.

This being so, we are going to define, in the torsor Σ_i under $\mathcal{H}_i$ of splittings of D_i^* over D_i, a sub-$K_i^{*\mathrm{i1}}$-torsor (i.e. an element of Σ_i/K_i^*). For this,

[scan 75]
d1 m179

Marginal note. m179 make a general local argument, dropping the index i.

Let us consider more generally the case of a field k $(= K_i)$ of characteristic 0, and of a d4 k-algebra $\mathcal{O}$ which is a henselian gauge[i3] with residue field k. let L be the fraction field of $\mathcal{O}$[i4] We are going, for every[y] uniformizer t of $\mathcal{O}$, to define a section (γ, λ) of the|of the d5 d6 groupoid|groupoids of algebraic closures of L, to that of universal coverings of $\mathrm{Spec}(\mathcal{O})|\,\text{fét}(\mathcal{O})$ or, what amounts to the same thing, of algebraic closures of k. For this,

let

$$\mathcal{O}(n, t|s) = \mathcal{O}[T_n]/(T_n^n - s), \quad \text{and}$$
$$\mathcal{O}(\infty, t) = \varinjlim_n \mathcal{O}(n, t), \quad \text{by } T_{n\,t|s} \mapsto T^m_{mn\,t|s}.$$

d7 d8 $L(n,t) = \mathcal{O}(n,t) \otimes_{\mathcal{O}} K =$ fraction field of $\mathcal{O}(n,t)$, $L(\infty, t) = \varinjlim_n L(n,t)$ the fraction field of $\mathcal{O}(\infty, t)$. This is 74

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 76]

[p. 36]

an algebraic extension of L, and for ever[y] [d1] finite, or ind-finite extension[i1] k' of k, putting $\mathcal{O}' = \mathcal{O} \otimes_k k'$ (which is also a henselian gauge over k' with residue field k', with fraction field $L' \simeq L \otimes_k k'$), we have canonical isomorphisms[i2] [d2]

$$\mathcal{O}(n|\infty, t) \otimes_{\mathcal{O}} \mathcal{O}' \simeq \mathcal{O}'(n|\infty, t)$$

$$\mathcal{O}(\infty, t) \otimes_{\mathcal{O}} \mathcal{O}' \simeq \mathcal{O}'(\infty, t)$$

whence

$$L(n|\infty, t) \otimes_k \overline{k}'|k' \simeq L'(n|\infty, t)$$

$$L(\infty, t) \otimes_k k' \simeq L'(\infty, t)$$

Now if $k'|\overline{k}'$ is algebraically closed, [d3] $\mathcal{O}'$ strictly henselian, we know that $L'(\infty, t)$ is then algebraically closed. Besides [d4] since $\overline{k}'|k' \subset \mathcal{O}'(\infty, t) \subset L'(\infty, t)$, in this case $k\ k'$ [d5] is identified with the algebraic closure $\overline{k}$[i3] of k in $L'(\infty, t) = \overline{L}$. So we have indeed found a section of Π_{D^*} over Π_D.

But if we replace s by $s' = su^n$, with $u \in \mathcal{O}^*$, we find isomorphisms

$$\lambda(n, u) : \begin{array}{ccc} \mathcal{O}(n, s) & \longrightarrow & \mathcal{O}(n, s') \\ \| & & \| \\ \mathcal{O}[T_n]/(T_n^n - s) & & \mathcal{O}[T_n]/(T_n^n - s') \end{array}$$

by $T_n \to uT_n$ whence by passing to the limit

$$\lambda(\infty, u|n) : \mathcal{O}(\infty, s) \longrightarrow \mathcal{O}(\infty, s')$$

inducing $L(\infty, s) \xrightarrow{\sim} L(\infty, s')$ an isomorphism of extensions of L[i4] 75

[scan 77]

whence an isomorphism between the corresponding sections of the Π_L over Π_k. This implies that if s, s' differ by a $u|v \in \mathcal{O}^*$ such that its image in k is 1 [d1] i.e. $u|v \in 1 + m$[i1] (which is a divisible subgroup of $\mathcal{O}^*$] then s, s' define isomorphic sections. Thus we find a canonical map

$$\begin{array}{ccc} & & \text{isomorphism classes of sections of} \\ (m/m^2)^* & \to & \Pi_L \text{ over } \Pi_k \quad \text{i.e. of} \\ & & \mathrm{Gal}(\overline{K}/L) \to \mathrm{Gal}(\overline{k}/k) \\ (\text{set of} & & \\ \text{bases of } m/m^2) & & (\text{which is a torsor under} \\ \text{which is a} & & H^1(\mathrm{Gal}(\overline{k}/k), T(\overline{k})) \\ \text{torsor under} & & \text{i.e. under } H^1(k, T(G_m)) \ldots) \\ k^* & & \end{array}$$

We see at once that this map is compatible with the homomorphism

$$\Theta : k^* \to H^1(k, T(G_m))$$

on the groups acting on these torsors. In the case where this homomorphism is injective (for example k [d3] of finite type over $\mathbf{Q}$) we thus find an embedding of m/m^2 as a sub $\Theta(k^*)$-torsor of the $H^1(k, T(G_m))$-torsor 76

[p. 37]

of splittings of Π_{D^*} ($\simeq$ groupoid of algebraic closures of L)[i1] over Π_D ($\simeq$ groupoid of algebraic closures of k).

Returning to the case of the [d1] $\Pi_{D^*} \to \Pi_U \to \Pi_e$ $\kappa|K \ldots$, and of the [d2]

$$\mathcal{D} : T(\overline{K}^*) \xrightarrow{\kappa_i} \mathcal{E}_i \hookrightarrow \mathcal{E} \xrightarrow{p} \Gamma$$

which make them explicit, we thus find an additional structure on $\mathcal{E}$ or $\mathcal{D}$ via [d3] the extensions $\mathcal{E}_i$ of $\Gamma_i \subset \Gamma$ by $T(\overline{K}^*)$, namely [d4] $\forall i \in I$[i2] sub-K_i^*-torsors in the torsor under $H^1(K_i, T(G_m)) \simeq \varprojlim (K_i^*)_n$ of classes of[i3] splittings of $\mathcal{E}_i$. We ought to make explicit the behavior of this additional structure with respect to morphisms (coming from geometric situations) and the relation with the norm of differential 1-forms — I'm too lazy to make it explicit at length and in detail!

The new thing I retain above all is that for $I \neq \emptyset$ and the $\mathcal{E}_i \to \Gamma$ surjective (to simplify), we find $\forall i$[i4] a|some "transcendental|transcendental family|families" of splittings of $\mathcal{E} \to \Gamma$ (via splittings of $\mathcal{E}_i$ over Γ) — essential[ly] indexed 77

[p. 38]

10. Adjustment of the hypotheses (remorse).

I realize that in the definition of the morphisms $(X', S') \xrightarrow{f} (X, S)$, the hypothesis $f^{-1}(S)_{\text{red}} = S'$ is too narrow — we must take arbitrary morphisms $f : X'\backslash S' \to X\backslash S$ (extending of course to $\hat{f} : X' \to X$). We will thus have $S' \supset \hat{f}^{-1}(S)_{\text{red}}$, but S' may be strictly larger than $\hat{f}^{-1}(S)_{\text{red}}$. We must then adjust the description of the "messy category" accordingly — the objects remain the diagrams of groupoids

$$\mathcal{D} : \Pi_{D^*} \to \Pi_U \to \Pi_e$$

(plus Kummer datum) but a morphism f from a $\mathcal{D}'$ into a $\mathcal{D}$ no longer necessarily defines a $\Pi'_{D^*} \to \Pi_{D^*}$ (in addition to $\Pi'_U \to \Pi_U$) one must specify a subset I'_f of $I' = \pi_0(\Pi'_{D^*})$, and specify only

$$\Pi'_{D^*, I'_f} \xrightarrow{f_{D^*}} \Pi_{D^*}$$

(with commutation datum α_{D^*U}[i1] relative to the square with f_U). Of course, in the description in terms of $\mathcal{E}', \mathcal{E}$ etc., we require that for $i' \in I'\backslash I'_f$, $f_{\mathcal{E}} : \mathcal{E}' \to \mathcal{E}$ is trivial on $\mathcal{E}'_{i'} \subset \mathcal{E}'$ — and τ is defined as $I'_f \to I$; some|the data relating to the $i' \in$ 79

[scan 81]

$I'_{f'}$ $(f_{i'} : \mathcal{E}_{i'} \longrightarrow \mathcal{E}_{i=\tau(i')},$ the $\alpha_{i'} \in \mathcal{E})$ are the same as in the case considered previously.

N.B. This means in fact that we begin to "plug the holes" [d1] (of X') corresponding to the $i' \in I' \setminus I'_{f'}$, by replacing $\mathcal{E}'$ by the [d2]quotient group of $\mathcal{E}'$ by the invariant subgroup generated by the $L_{i'} = \kappa_{i'}(T(\overline{K}))$ $(i' \in I' \setminus I'_{f'})$, and [d3] $\mathcal{E}_{i'}$ $(i' \in I'_{f'})$ by their images in the said quotient group, and forgetting [d4] $I' \setminus I'_{f'}$, i.e. replacing I' by $I'_{f'}$.

[To do things properly, we would have to express these operations also at the level of diagrams of groupoids

$$\Pi'_{D^*} \longrightarrow \Pi'_U \longrightarrow \Pi'_e|\Pi_e$$

...].

This means then that in fact, we have brought ourselves back to the situation considered at the beginning, where $S' = \hat{f}^{-1}(S)$... So in the end the difference between the two points of view is not enormous, and [d6]the one[i1] adopted at the beginning has the advantage of greater simplicity (everything is relative!) 80

[p. 39]

11. Conditions on the systems of [d1]groupoids[i1] obtained from geometric situations.

We have already mentioned some in passing, for example that the kernel groups of $\Pi_{D^*} - \Pi_e$ are abelian (with the Kummer isomorphism κ) and that the images are open subgroups, and the = for the image of the [d2] π_1 in $\Pi_U - \Pi_e$. We are going to spell out again and make precise[i2] this in the framework of the interpretation in terms of

$$T(\overline{K}) \xrightarrow{\kappa_i} \mathcal{E}_i \xhookrightarrow{\rho_i} \mathcal{E} \xrightarrow{p} \Gamma$$

(the "dimension 1" case — we do not exclude the case $I = \emptyset$ — the "dimension 0" case being trivial…)

a) The image Σ[i3] of p is open, more precisely exists open subgroup $\Gamma' \subset \Gamma$ over which $\mathcal{E}$ has a section [and even an "admissible section" in a sense to be defined later — so as to exclude the "trivial" sections coming from the $\mathcal{E}_i$…].

b) The image Σ_i of $\mathcal{E}_i$ in Γ is open, and the extension $\mathcal{E}_i$ of Σ_i by L_i ($\simeq T(\overline{K})$) is trivial. [In fact, we have a privileged[i4] class of splittings, called "algebraic", forming a torsor under $K_i^* \hookrightarrow \varprojlim (K_i^{*n})_n | (K_i^*)_n$, cf. number 9]|? — but 81

[scan 83]

we are not going to consider for the moment[i1] this additional piece of structure…)
d1

The rest of the [d2]conditions[i2] essentially concerns the structure of the groups $\pi = \mathrm{Ker}(p : \mathcal{E} \to \Gamma)$ with its conjugacy classes of[i3] subgroups (or rather the outer homomorphisms $\kappa_i : T\,(= T(\overline{K}^*)) \longrightarrow \pi$, and the way Σ operates by outer automorphisms on π. These conditions are expressed in a particularly simple way when the $\Sigma_i \subset \Gamma$ are $= \Gamma$ ("the points of S all[i4] rational over K") i.e. $\mathcal{E}_i \to \Gamma$ surjective, a fortiori $\Sigma = \Gamma$ i.e. $\mathcal{E} \to \Gamma$ surjective. We are going to restrict ourselves to this case. The general case follows by a finite extension of the base field [over which [d4]each[i5] points of S not rational over K i.e. each $\Sigma_i \neq \Gamma$[i6] [d5]gives|give rise[i7] to n_i points, [d6] $n_i = [\Gamma : \Sigma_i]$ } — and $X_{K'}$ [d7] split|splits into $n = (\Gamma : \Sigma)$ connected components which are geometrically connected] — but I am too lazy to spell out as I should, in the context of groupoids or of [d8] homomorphisms of profinite groups, the operation of extension of base fields… It is understood that 82

[p. 40]

the conditions I am going to describe will be invariant under extension of the|of the base field.

d1

c) $\forall i^{\text{d2}}$, the outer homomorphism

$$\kappa_i : T \longrightarrow \pi$$

is compatible with the outer action of Γ (operating on T by the cyclotomic character χ, and on π thanks to the extension $\mathcal{E}$ of Γ by π). In other words, for $\forall g \in \mathcal{E}$, exists an $\underline{\alpha \in \pi}$ (N.B. not just $\alpha \in \mathcal{E}$!) such that we have,

$$\text{int}(g)\kappa_i(\xi|\zeta) = \text{int}(\alpha)\kappa_i(\chi(p(g))\xi|\zeta)$$

i.e.

$$\text{int}(\alpha^{-1}g)\kappa_i(\xi|\zeta) = \kappa_i(\chi(p(g))\xi|\zeta)$$

This means then that 1°) $\alpha^{-1}g$ normalizes $L_i = \kappa_i(T)$. [and this means =, probably, that $\alpha^{-1}g \in \mathcal{E}_i$ — and that we can find such an $\alpha \in \pi$ such that $\alpha^{-1}g \in \mathcal{E}_i$[i1] comes from the hypothesis $\mathcal{E}_i \to \Gamma$ surjective — we take a $\beta \in \mathcal{E}_i$ $=\alpha^{-1}g$[i2] having the = image as g in Γ and we take $\alpha = g\beta^{-1}$] and that 2°) the inner[i3] action of $\beta = \alpha^{-1}g$ on T is nothing other than by multiplication by $\chi(g) = \chi(\beta)$ — which (for $\beta \in \mathcal{E}_i$) is nothing other than the 83

[scan 85]

condition already spelled out that the group homomorphism $\kappa_i : T \to \mathcal{E}_i$ is compatible with the action of $\mathcal{E}_i$, operating on T via $\chi \circ p \mid \mathcal{E}_i$, and on itself by inner automorphisms.

So condition c) is not really new — I spell it out again in slightly different terms, because of its importance. It implies that the operation m192

Marginal note. m192

of Γ on π is very nontrivial (since $\chi : \Gamma \to \widehat{\mathbb{Z}}^*$ has an open image!) — it was not = obvious a priori (without deep arithmetic reasons!)[i1] — in view of the structure of π that we are going to give — that there exist such operations of Γ on a π!

This condition will be supplemented by a nontriviality condition in the style of Weil.

d) $\exists \eta \in T^*$. (a basis of T), and $\alpha_i \in \pi$ (in order to conjugate κ_i into $\kappa'_i = \mathrm{int}(\alpha_i) \circ \kappa_i$) finally an integer $g \geq 0$ and elements $x_i, y_i \in \pi$ $(1 \leq i \leq g)$, such that we have 84

[scan 86]

[p. 41]

1°) the $\kappa'_i(\eta)$, d1 and the $x_i, y_i | x_j, y_j$ generate the profinite group π

2°) They satisfy the relation

$$\boxed{[x_1, y_1].[x_2, y_2] \ldots [x_g, y_g]\, \kappa'_1(\eta)\kappa'_2(\eta) \ldots \kappa'_{\nu|n}(\eta) = 1}$$

3°) This relation, with the generators considered describes π (as a profinite group)[i1] by generators and relations…

N.B. We know that under these conditions, g is uniquely determined, for example by the fact that $\pi_{ab}/\sum \kappa_i(T)$ is a free $\widehat{\mathbb{Z}}$-module of rank $2g$ — π_{ab} being free of rank $2g + \nu - 1$ where $\nu = \mathrm{card}(I)$.

For the choice of η, we know that if η works, then $\forall\ \chi(\alpha)\eta$ too (where $\alpha \in \Gamma$) — up to taking conjugates. So the η that work d3 contain a subtorsorof T^{*}[i2] (under the open subgroup $\chi(\Gamma)$ of $\widehat{\mathbb{Z}}^*$.

[scan 87]

[p. 42]

(therefore|in $\chi : \Gamma \to \widehat{\mathbb{Z}}^*$ epimorphism)

d1 In fact, since the structure of the group π is independent of K, taking $K = \mathbb{Q}$ (and admitting that there exists a smooth projective geometrically connected curve of genus g over $\mathbb{Q}$, having ν rational points over $\mathbb{Q}$!), we find that if the ℓ_i, d2 $(1 \leq i \leq \nu)$ d4 fit into a privileged system of generators (with some x_α, y_α) then for $\forall \rho \in \widehat{\mathbb{Z}}^*$, we can find conjugates ℓ_i' of the ℓ_i^ρ which fit in the = way. Even for $\rho = -1$ this is not entirely trivial…

d5 Finally, we are going to state a draconian condition of nontriviality of the operation of Γ on π. Let $\mathcal{E}'$ be a subgroup open (hence[i2] of finite index) of $\mathcal{E}$, $\pi' = \pi \cap \mathcal{E}' = \mathrm{Ker}(\mathcal{E}' \to \Gamma')$[i3] d6 86

Apparatus for this scan

140-2-s087-D001 *deletion. Manuscript:* hence also the $\kappa_i'(\chi(g)\eta)$. Taking $K = \mathbb{Q}$, we thus find by arithmetic means:

Proposition Let π be the free P-group on $\nu - 1|\nu$ generators (generated by generators $\ell_1, \ldots, \ell_\nu$ satisfying the defining relation $\prod \ell_i = 1$. Then for every $\alpha \in \widehat{\mathbb{Z}}^*$, we still have $\prod \ell_i^\alpha = 1$, and the $\ell_i' = \ell_i^\alpha$ with this relation describe the profinite group π.

[scan 88]

Γ' the image of $\mathcal{E}'$ in Γ. We thus get an extension of Γ' $(= \mathrm{Gal}(\overline{K}'/K'))$ over π', hence also by $(\pi'_{ab})_{(\ell)}$ (ℓ being a prime number), which is (we know this by d)) a free $\mathbb{Z}_\ell$-module of finite type, on which Γ' operates[i1]

[With a little work, we should be able to put on $\mathcal{E}' \to \Gamma$ a "loop structure" i.e. some $\mathcal{E}'_{i'}$, as for $\mathcal{E}$, and describe in $(\pi'_{ab})_{(\ell)}$ the sum[i2] of the images of the [d1] $L'_{i'}$, on which Γ' operates therefore[i3] via the character χ.
m197

Marginal note. [m197] This is done very elegantly in the setting

$$\Pi_{D^*} \longrightarrow \Pi_U \longrightarrow \Pi_e$$

We are interested in the quotient of $(\pi'_{ab})_{(\ell)}$ by this submodule|these submodules which is relatively trivial (the "abelian variety" part of the ℓ-adic module under consideration). This being said

ⓒ we require that the representation of Γ' on this be "pure of weight 1" — [d2] and that the characteristic polynomials of the Frobenius elements (which have coefficients $\in \mathbb{Z}$, not just $\in \mathbb{Z}_\ell$) be independent of ℓ.
m198

Marginal note. [m198]

12. The topological analogy

Let X be a compact orientable (topological) [d1]surface[i1], S a finite subset of X. If X is connected, we consider the set ω[i2] of the|its two orientations, we use it to twist the group $\mathbb{Z}$, whence a group T

$$T = \mathbb{Z} \underset{\pm 1}{\wedge} \{\omega\}|\omega.$$

isomorphic (noncanonically) to $\mathbb{Z}$. More generally, suppose given such a group T, i.e. an $\omega \in \mathrm{ObEns}_2$[i3] — a T-orientation of X will by definition be an element of the set $\mathrm{Or}(X) \underset{\{\pm 1\}}{\wedge} \omega$.

[in the preceding case, X will thus be canonically T-oriented…]

Let us consider the fundamental groupoid of $X \setminus S = U$, say Π_U, and the fundamental groupoid Π_{D^*}[i4] of germs of spaces of X around S, deprived of S [d2] groupoids ?[i5] (of germs of universal coverings of $X \setminus S$ in a neighborhood of S). We thus have a canonical functor

$$\Pi_{D^*} \longrightarrow \Pi_U$$

and on the other hand, [d3] if X is T-oriented, we have an additional structure 88

Scans 91–100

[scan 91]

[p. 44]

$\exists$ generator $g \in T$ (i.e. $g \in T^*$) and an order i_1–i_ν[i1] on the set I, [d1] conjugates $l'_i|l'_{i_\alpha}$ of the $\kappa_{i_\alpha}(g)$, and $g \in \mathbb{N}$ and $x_\alpha, y_\alpha \in \pi$ $(1 \leq \alpha \leq g)$ such that we have

$$\left(\prod_1^g [x_\alpha, y_\alpha]\right) \prod_1^\nu l_i = 1$$

and that this be a defining relation of π.

There is however[i2] a grain of salt for $I = \emptyset$ (in which case T serves no purpose apparently[i3] (in the groupoid description of $(X, S) \simeq|= (X, \emptyset) = X$) one must then, †[d2] place of the "Kummerian" data κ[i4], give oneself

$$H^2(\pi, \mathbb{Z}) \overset{\kappa}{\simeq} T$$

m202

Marginal note. [m202] One must introduce therefore[i5] this as an additional datum, in the definition of groups with loops the exclusion of the cases $X_0 \simeq S^2$ (in the case of empty S) is then particularly convincing.

Finally, one must [d3] (even|= with this grain of salt) exclude the case $X = S^2$, $S = \emptyset$ (as a connected component) — i.e. on the groups side, the case of a component of Π_U where[i6] $\pi = (1)$ [d4] and $I = \emptyset$. [If I remember correctly, there is no reason to exclude (S^2, pt) (i.e. $X \setminus S = U \simeq \mathbb{R}^2 \simeq \mathbb{E}^1_{\mathbb{C}|e}$) 90

where nevertheless we have $\pi = 0$. But except in these two cases, [d1] (corresponding to the case $g = 0$, $\nu = 1$) the homomorphism $\kappa_i : T \longrightarrow \pi$ is injective. If $T = \mathbb{Z}$ the datum of the κ_i is equivalent to that of elements $l_i \in \pi$, and we recover the usual definition of loop structures.

This is made explicit in the thesis of Yves Ladegaillerie — what is missing there, is (among other things) the consideration of arrows between (X, S) other than homeomorphisms (modulo isotopies) ; for example maps [d2] [d3] $X' \xrightarrow{f} X$ such that $S' = f^{-1}(S)$ [and that X' be étale over $X \setminus S$, if one insists!], which reduces to the preceding case — the more[i1] general case where one assumes only that X' is a ramified covering of X (possibly ramified also outside S') and $S' \supset f^{-1}(S)$ (but S' possibly larger) would call for 91

[p. 45]

a careful study, with an ad-hoc notion of isotopy ....

Another important direction (notably for the study of the|of the unoriented, nonorientable case) is the introduction of finite groups of homeomorphisms, not necessarily respecting the orientation. To treat the case of a change of orientation, note that in the groupoid description $(\Pi_{D^*} \longrightarrow \Pi_U, \kappa)$ of a (X, S) that is T-oriented, the passage to the opposite orientation is expressed by keeping $\Pi_{D^*} \longrightarrow \Pi_U$ as is, and replacing κ by $\bar{\kappa} = \kappa^{-1}$

$$\bar{\kappa}(\zeta|\xi) = \kappa(-\zeta|\xi) = \kappa(\zeta|\xi)^{-1}$$

(If $T = \mathbb{Z}$, on[i1] the system $(\pi, (l_i))$, this amounts to replacing the l_i by the l_i^{-1} ...) [m205]

Marginal note. [m205] and ditto (if $I = \emptyset$) for $\kappa : T \simeq H^2(\pi, \mathbb{Z})$ replaced by $-\kappa$.

Let then Γ be a group (a priori not necessarily finite) which operates on (X, S), hence on $U = X \setminus S$ and on Π_U, Π_{D^*}.[i2] We then find mixed fundamental[i3] groupoids [d1] by the well-known construction 92

[p. 46]

that I have in mind with the "arithmetic" case makes this reduction inopportune in the general case (for in the arithmetic †[d1], we do not restrict ourselves either to the case where $\Sigma = \Gamma$ i.e. $\mathcal{E} \longrightarrow \Gamma$ surjective, i.e. the connected component[i1] X geometric- ally connected over K). Note here[i2] that (X, S, Γ) is recovered from the $(X_0, S_0, \Gamma_0 = \Sigma)$ as an amalgamated sum

$$X = X_0 \wedge|\widehat{\times}_{\Sigma}\Gamma \quad ....$$

When we express (for $\Pi_{U|X,\Gamma}$ connected) the situation in terms of group theory, we therefore find [d2] a mixed fundamental group [d3]

$$\mathcal{E}_{U|X,\Gamma} = \pi_1(U, \Gamma)$$

and a homomorphism

$$\mathcal{E}_{U,\Gamma} \longrightarrow \Gamma$$

— (Surjective iff [d4] U connected (we have $\Gamma/\Sigma \simeq \pi_0(U)$)[i3]) finally a set of indices[i4] [d5] I ($\simeq S/\Gamma \simeq \pi_0(\Pi_{D^*,\Gamma})$) and mixed fundamental groups 94

$$\mathcal{E}_i \xrightarrow{\sim} \pi_1|\Pi_1(D_i^*, \Gamma) \simeq \pi_1(D_{i_0}^*, \Sigma_{i_0}|\Gamma_{i_0})$$

where $D_{i_0}^*$ is a connected component of the punctured multidisk D_i^* (corresponding to the choice of an $s_i \in S$)[i1], and where $\Sigma_{i_0}|\Gamma_{i_0} \subset \Gamma$ is its stabilizer (i.e. the stabilizer of s_i in Γ), which is [d1] (if Γ_i is finite and[i2] operates faithfully in a neighborhood of s_i) a cyclic or dihedral group ... We therefore find, if X is T oriented|oriented, an extension of Γ_{i_0} by T, the homomorphism $\mathcal{E}_i \longrightarrow \Sigma_{i_0}|\Gamma_{i_0} \subset \Gamma|\Gamma_i$ being induced of course via $\mathcal{E}_{U,\Gamma} \longrightarrow \Gamma$ and $\mathcal{E}_i \longrightarrow \mathcal{E}_{U,\Gamma}$.

One must also[i3] link the action of Γ on X to the orientation of X — for this we suppose given a character

$$\chi : \Gamma \longrightarrow \mathbb{Z}^* = \{\pm 1\}$$

and require that for $g \in \Gamma$, g_X preserve the orientation if $\chi(g) = 1$, reverse it if $\chi(g) = -1$. This implies that [d2]we have an|the homomorphism or[i4] isomorphism

[p. 47]

T being regarded as a local system on $\Pi_{\Gamma,e}$ [d1] i.e. as a Γ-group, thanks to the action of Γ via the character χ. It amounts to the same to say that $\forall i \in I$[i1] the map [d2]

$$\kappa_i : T \xrightarrow{\sim} L_i = \mathrm{Ker}(\mathcal{E}_i \longrightarrow \Gamma)$$

as a homomorphism from T to $\mathcal{E}_i$ is compatible with the action of $\mathcal{E}_i$ (operating on T via χp_i ($p_i : \mathcal{E}_i \longrightarrow \Gamma$)), [illeg. 1] and on itself by inner automorphisms ...

If we exclude the case where (X_0, S_0) is $\simeq (S^2, \emptyset)$ or $(S^2, 1 \text{ pt})$ (i.e. the case $\pi = 0$), the $\kappa_i : T \longrightarrow \pi$ are injective, hence also the $\mathcal{E}_i \longrightarrow \mathcal{E}_{U,\Gamma}$, hence the $\mathcal{E}_i$ can be regarded as subgroups of $\mathcal{E}_{U,\Gamma}$.

§ Here it [d3] would be particularly inadvisable (even|= if we assume $\Sigma = \Gamma$ i.e. $X = X_0$ i.e. X connected) to suppose that the Γ_i be|are $= \Gamma$ i.e. that the $s \in S$ are fixed by Γ ! 96

[p. 48]

d1 Thus, the operation of Σ on S_0 (hence of Γ on $S = S_0 \wedge_\Sigma \Gamma$) is known, from the outer operation of $\Sigma \subset \Gamma$ on π endowed with its "T-loop" structure d2 (i.e. the outer homomorphisms $\kappa_s : T \longrightarrow \pi$) — hence also $I = S_0/\Sigma \simeq S/\Gamma$.

Can we reconstruct $\mathcal{E}_i$ $(i \in I)$i1 from the d3 extension structure? We see, d4 d5 by virtue of the choices made, that if $i \in I$ (hence i an orbit of Σ in S_0) $\exists\ s \in i$ such that $\mathrm{Ker}(\mathcal{E}_i \longrightarrow \Gamma)$ is none other than $L_s = \kappa_s(T)$, and we therefore have $\mathcal{E}_i \subset \mathrm{Norm}_\mathcal{E}(L_s)$, But we have

$$\mathrm{Norm}_\mathcal{E}(L_s) \cap \pi = \mathrm{Norm}_\pi(L_s) = L_s$$

$= \mid \neq \mathcal{E}_i \cap \pi$, and on the other hand the image of $\mathrm{Norm}_\mathcal{E}(L_s)$ in $\Sigma \subset \Gamma$ is not d6 $\subset$i2 Σ_s = stabilizer d7 s ini3 Σ = Image of $\mathcal{E}_i$ in Σ, and|hence in summary

$$\mathcal{E}_i = \mathrm{Norm}_\mathcal{E}(L_s)$$

[scan 100]

Conversely, the datum of $\mathcal{E} \longrightarrow \Gamma$ and of the $\mathcal{E}_i$, $\kappa_i : T \longrightarrow \mathcal{E}_i$ gives back the loop structure of π, by taking the κ_i and all their distinct[i1] outer conjugates by the $\alpha \in \Sigma$ (modified by $\chi(\alpha)$ ...).

Thus the datum of the[i2] situation $\mathcal{E} \xrightarrow{p} \Gamma$, $\mathcal{E}_i \subset \mathcal{E}$ [d1] (family of subgroups, each defined modulo conjugation in $\mathcal{E}$) is equivalent to the datum of

a) $\pi = \operatorname{Ker} p$, with its T-[i3]loop structure ([d2]finite set of outer homomorphisms from[i4] T to π)

b) A sub-[d3] group $\Sigma \subset \Gamma$, and a homomorphism

$$\Sigma \longrightarrow \text{extended Teichmüller of } \pi$$

(outer automorphisms of π, respecting the loop structure modulo sign compatible with the character $\chi|\Sigma$ and the "sign" character on extended Teichmüller. In fact, (X, S, Γ), or (U, Γ), defines π only as an outer group with T-loops[i5] on which Γ operates in a way compatible with χ. 99

Scans 101–110

[scan 101]

[p. 49] In summary, we have a [d1]canonical[i1] functor Isotopic category of (X, S, Γ), X compact surface [d2], T oriented, S discrete subset, Γ operating by χ-automorphisms ($\sigma \in \Gamma$[i2]preserving|preserves the orientation if $\chi(\sigma) = +1$, reversing it if $\chi(g) = -1$), Γ transitive on $\Pi_0(X)$, [d3] and if (X_0, S_0) is a connected component of (X, S), we want that [d4]if $X_0 \simeq S^2$, we[i3] have $\operatorname{card} S_0 \geq 3$ [d5]. [d6] [m215]

Marginal note. [m215] arrows: isotopy classes of homeomorphisms respecting all the structures.

Category of outer groups with T-[i4]loops π, π noncommutative (i.e. $\pi \neq 0, \mathbb{Z}$);[i5] on which a subgroup $\Sigma \subset \Gamma$ of Γ operates[i6] (this description being equivalent: a description in terms of systems of groupoids

$$\Pi_{D^*,\Gamma} \longrightarrow \Pi_{U,\Gamma} \longrightarrow \Pi_{e,\Gamma} \quad \text{and } \kappa \dots,$$

more conceptual in certain contexts…). [m216]

Marginal note. [m216] Beware of the case $S = \emptyset$ in the definition of the structures: the [illeg. 1] (datum of $H^2(\pi, \mathbb{Z}) \overset{\kappa}{\simeq} T$); we must of course take into account during the action of Σ on $H^2(\pi, \mathbb{Z})$ [d7] (via its outer action on π) and on T (via χ) and require the compatibility.

[d8] I presume that the proof of the fact that this functor is fully faithful presents no essential difficulties, [m217]

Marginal note. [m217] It would really be worth doing it very carefully…

using what is known for $\Gamma = 1$. But the fact that, for|†[d9] Γ a given finite group, [d10]it is essential[ly] surjective[i7] 100

[scan 102]

is an open problem on which people are stumped. Of course we may assume $\Sigma = \Gamma$, and $\Gamma \subset$ extended Teichmüller[i1] and the question is whether every finite subgroup of the extended Teichmüller is realized as a group operating on (X_0, S_0) [illeg. 1] in an essentially unique way. More precisely, if [d1] $A =$ group of [d2]homeomorphisms (or diffeomorphisms, if X_0 is differentiable) of X_0, A^0 its connected component|of (N.B. A^0 is contractible, [d3]in[i2] the anabelian cases) hence $A/A^0 = \mathcal{T}_{g,\nu}$ (Teichmüller group for genus g and ν holes), the question comes down to: this whether for every homomorphism from a finite group Σ into [d4] $\mathcal{T}_{g,\nu}$, (we may assume $\Sigma \subset \mathcal{T}_{g,\nu}$), it lifts to a homomorphism into A, and whether two such liftings are conjugate by an $a \in A^0$ (isotopy in the strict sense[i3] of two liftings $\sim$).

Having arrived at such a simple [d5]reinterpretation|interpretation[i4] of the 1-category ("1-isotopic") deduced from the 2-category of systems $(\Pi_{D^*,\Gamma} \longrightarrow \Pi_{U,\Gamma} \longrightarrow \Pi_{e,\Gamma}, \kappa)$, in terms 101

class Θ^{i1} of isomorphisms

$$\pi' \overset{u}{\longrightarrow} \pi,$$

we associate an "inverse image" functor Ens(π) $\longrightarrow$ Ens(π'), defined up to unique isomorphism. Let us consider for every u in the class Θ, the functor "u-restriction of operations"

$$\mathrm{Ens}(\pi) \overset{u^*}{\longrightarrow} \mathrm{Ens}(\pi')$$

[which [d1]defines,[i2] therefore, with $u_* = (u^{-1})^*$,[i3] an [d2]equivalence[i4] of the Topoi

$$B_{\pi'} \overset{u_\bullet}{\underset{\sim}{\longrightarrow}} B_\pi$$

] We shall, between these [d3]equivalences[i5], for $u \in \Theta$,[i6] define a transitive system of isomorphisms (which therefore lets us identify them with each other!).

Let|Let $u, u' \in \Theta$, whence u^*, u'^*; we have by hypothesis [d4] a $g \in \pi$ such that $u' = \mathrm{int}(g) \circ u$, furthermore g is determined modulo an element of $\mathrm{Centr}_\pi u(\pi') = \mathrm{Centr}(\pi) = 1$; so here g is unique. But g can be used to define a functorial isomorphism [d5]between[i7]

$$i_{u',u} : u^* \xrightarrow{\sim} u'^*$$

by taking, for $E \in \mathrm{Ob}\,\mathrm{Ens}(\pi)$,

$$i_{u',u}(E) : \underset{\|}{u^*(E)} \longrightarrow \underset{\|}{u'^*(E)}, \qquad i_{u',u}(E) = g_E.$$
$$E \qquad\qquad E$$

[scan 105]

[p. 51] N.B. The argument works for every conjugacy class of homomorphisms of groups[i1] $\pi' \longrightarrow \pi$ (i.e. every outer homomorphism) whose centralizer in π is reduced to 1 (which for an epimorphism reduces to the hypothesis $\mathrm{Centr}(\pi) = 1$). [m222]

Marginal note. [m222] works for anabelian loops|anabelian groups with loops, and the homomorphisms of such whose image is of finite index… (for the centralizer in such a group π of a subgroup of finite index is still reduced to e|reduced to 1).

If now a group Σ operates on the outer group π[i2], then by the preceding result we can say that it also operates on the topos B_π, whence a topos $B_{\pi,\Gamma}$,[i3] (we can also say that [d1] Since $\mathrm{Centr}(\pi) = 1$) the operation of [d2]Σ on π defines an extension $\mathcal{E}$ of Σ by π, whence a topos $B_{\pi,\Gamma} = B_{\mathcal{E}}$, [d3] We recover[i4] of course also $B_{\pi,\Gamma} \longrightarrow B_\Gamma$. To reassure ourselves, we should make sure that if we have a homomorphism of outer groups $\pi' \overset{\Theta}{\longrightarrow} \pi$ commuting with the action of a Σ, with $\mathrm{Centr}_\pi(\Theta) = (1)$, then there exists a $\Theta_\Gamma : B_{\pi',\Gamma} \longrightarrow B_{\pi,\Gamma}$ defined up to canonical isomorphism. Now every $u \in \Theta$ defines a homomorphism of extensions u_Γ (of Σ by π' resp. π)[i5] $\mathcal{E}' \longrightarrow \mathcal{E}$ above|below u, and if we pass from u to $u' = \mathrm{int}(g) \circ u$, we will have 104

$u'_\Gamma = \mathrm{int}_{\mathcal{E}}(g) \circ u_\Gamma$, and we finish as above, with uniqueness of g.

Now take an injective[i1] outer homomorphism

$$\Lambda = [\kappa] : T \longrightarrow \pi \qquad (T \text{ commutative}),$$

m225 (initial of "loops")

Marginal note. [m225] Injectivity in the case we are interested in follows from the anabelian hypothesis.

suppose that (for $\kappa \in [\kappa]$)

$$\mathrm{Centr}_\pi\, \kappa = \kappa(T)$$

(which does not depend on the|on the choice of κ in $[\kappa]$). I will then define a [d2] connected abelian groupoid Π_Λ[i2], and an isomorphism of its π_1 with T [d3] (hence a topos, which plays the role of $\widehat{\Pi}_{D|D^*}$). An object will be a $\kappa \in [\kappa]$. A homomorphism from κ to κ' will be an element $g \in \mathrm{Transp}_\pi(\kappa, \kappa')$. [d4] The composition of homomorphisms obvious. We do indeed get a connected groupoid, in which $\mathrm{Aut}(\kappa) = \mathrm{Centr}_\pi(\kappa) \overset{\text{by hypothesis}}{=} \kappa(T) \underset{\sim}{\overset{\kappa}{\leftarrow}} T$.

OK. Of course, we have a homomorphism $\Pi_\Lambda \longrightarrow$ one-point groupoid, hence on the classifying|classifying topoi defined by π[i4] $B_\Lambda \longrightarrow B_\pi$[i5]. We have to see the behavior of this 105

[scan 110]

It has become clear that in terms of an algebraic closure $\overline{K}$ of K, and of the profinite[i1] Galois group $\Gamma = \mathrm{Gal}(\overline{K}/K|k)$, the simplest description is in terms of outer groups with loops, and of outer actions of open[i2] subgroups $\Sigma \subset \Gamma$ on them. To be precise, [d1] we choose a connected component $\overline{X}_0$ of $\overline{X}$ (or what amounts to the =, $\overline{U}_0$ of $\overline{U} = (X \setminus S)_{\overline{K}}$), let Σ be its stabilizer in Γ (it is replaced by a conjugate, when we change $\overline{U}_0$). Then Σ operates on the scheme $\overline{U}_0|\overline{X}_0$, hence operates by outer automorphisms on its π_1 (considered as an outer group). Now on this there is a $T(\overline{K})$-[i3]loop structure, [d2]with as[i4] index set

$$I = S_0(\overline{K}) \subset \qquad S(\overline{K}) \qquad\qquad [\text{empty if|iff } S = \emptyset]$$

$$\wr|$$

$$S_0(\overline{K}) \wedge_\Sigma \Gamma$$

[p. 54]

d1 and the operation of Σi1 d2 on π is compatible with this loop structure, and the cyclotomic character $\chi : \Gamma \to \widehat{\mathbb{Z}}^*$ (rather, $\chi \mid \Sigma$). Thus the operation of Σ on π implies its action on I, whence $S(\overline{K}) \simeq I_0|\overline{S}_0 \wedge_\Sigma \Gamma$ as a Σ-set — we thus recover the étale K-scheme S.

But better, we recover the whole diagram

$$\Pi_{\overline{D}_0^*} \longrightarrow [\Pi_{\overline{U}_0} \to |-]\, \Pi_{\overline{U}} \longrightarrow \Pi_e$$

and the operation of Σ on it, whence the diagram of topoi of coverings d3i2 — or if we prefer, the diagram

$$\Pi_{D^*} \longrightarrow \Pi_U \longrightarrow \Pi_e$$

(with the notation from the beginning of these notes, which here would become $\Pi_{D^*,\Gamma} \to \Pi_{U,\Gamma} \to \Pi_{e,\Gamma}$), plus of course K…

The morphisms $(X', S') \overset{f}{\to} (X, S)$ $[S' \supset f^{-1}(S)$, f dominant] d4 are described i3 d5 simply i4 (via the choice of an $\overline{X}_0'$ over an $\overline{X}_0$) d6 by i5 outer homomorphisms (159)

homomorphism $\pi' \to \pi$[i1] of groups with T-loops, the corresponding homomorphism $\hat{\pi}'|\tilde{\pi}' \to \tilde{\pi}$ also respect (for a suitable degree) the loop structure.

When we are interested [d1] anabelian systems $(\overline{X}, \overline{S})$ defined directly over $\overline{K}$, with $\overline{X}$ connected say, this is expressed by an outer group with T-loops, endowed with an action (not of Γ but of the) profinite group kernel defined by Γ. If we consider the [d2] "Γ-automorphisms" of such an object (formed of a $\gamma \in \Gamma$ and an outer[i2] automorphism f of π respecting the loop structure, f and γ being compatible in an obvious sense…), we find a group [d3] (pro-finite ???)[i3] G and a

homomorphism ("discrete" ???)[i4] $G \to \Gamma$ with image an open subgroup of Γ, and with kernel G_0[i5] the group of Galois|outer loop automorphisms of π which commute with the action of the|of the "kernel"[i6d4 d5] (which G_0 is conjecturally by the "messy conjecture", isomorphic to to the finite group[i7] $\mathrm{Aut}_{\overline{K}}(\overline{X}, \overline{S})$…). 113

In terms of this exact sequence

$$1 \longrightarrow |-G_0 \longrightarrow G \longrightarrow |-\Gamma$$

the "restriction of $(\overline{X}, \overline{S})$ to the field K" is therefore expressed (we hope, in a fully faithful way, if the messy conjecture is valid) by a splitting $\Gamma \to G$ of $G \to \Gamma$…

13bis. Return to the notion of group with loops

Let π be a group, $([L_i])_{i \in I}$ a family of conjugacy classes of subgroups of π. We say that this defines a [d1] "loop structure" on π [of type (g, ν)][i1], if $\exists\, g \in \mathbb{N}$, †[d2]$|\forall i \in I$ an $L_i \in [L_i]$, a generator

$l_i \in L_i$, elements $x_\alpha, y_\alpha \in \pi$ $(1 \leq \alpha \leq g)$ finally an order $i_1 \dots i_\nu$ on I ([d3] $\nu =$[i2] cardinality(I)), such that (putting $l_\alpha = l_{i_\alpha}$ for simplicity)

$$[x_1, y_1][x_2, y_2] \dots [x_g, y_g] l_1 \dots l_\nu = 0$$

is|are a presentation of the group π. We do not exclude a priori either the case $g = 0$, or the case $\nu = 0$, i.e. I empty.

We deduce from this:

a) If $\nu \neq 0$, π is free (on $2g + \nu - 1$ generators) — hence free nonabelian unless $g = 0$, $\nu \leq 2$ [d4]. 114

$$T_\pi \longrightarrow L_i$$

are isomorphisms. In the case $I \neq \emptyset$, we call T_π the $\mathbb{Z}$-module of orientations of π (endowed with the family of (L_i)) — we define, [d5] if $I = \emptyset$, $(\nu = 0)$, but $g \neq 0$[i2] (so $\pi \neq 1$ — the only case $\pi = 1$ is that where $g = 0$, $\nu = 0$ or 1) by the condition

$$T_\pi = \underbrace{H^2(\pi, \mathbb{Z})}_{\substack{\mathbb{Z}\text{-module} \\ \text{free of rank 1}}}{}^{\otimes -1}$$

[we shall establish below a relation between the two definitions of T_π]. Thus π_{ab} is free[i3] of rank $2g + \nu - 1$ if $\nu \neq 0$, $2g$ if $\nu = 0$. (so g is uniquely determined by π and $\nu = \operatorname{card} I$. [d6] 115

[p. 57]

Note that [if $\nu \neq 0$, and][i1] except for the "abelian" cases $g = 0$, $\nu = 1, 2$, the conjugacy classes of the L_i $(i \in I)$ are distinct, so the loop structure of π can be described as the datum of a set of ν conjugacy classes of subgroups of π. Moreover, [d1] we see that $\forall\, g \in \pi$ which normalizes an L_i centralizes it (this is obvious in any case for $\nu \geq 2$, for then $L_i \to \pi_{ab}$ is injective), which implies that the $\{L_i\}$ of one and the same class $[L_i]$ are canonically isomorphic to one another [d2] which gives an intrinsic meaning to the term $\prod L_i$ in the exact sequence above, and to the canonical isomorphism $T_\pi \to L_i$…[m243]

Marginal note. [m243] see separately the case $\nu = 1$: normalizer of the subgroup generated by $\prod[x_\alpha, y_\alpha]$, in the free group generated by the generators x_α, y_α…

If a group Σ operates on the loop structure $(\pi, ([L_i]))$ it operates on the invertible $\mathbb{Z}$-module T_π, whence a character

$$\chi : \Sigma \longrightarrow \mathbb{Z}^* = \{\pm 1\}$$

— [m244]

Marginal note. [m244] We assume from now on that we are in the anabelian case, or at least, we exclude $g = 0$, $\nu \leq 2$ 116

conversely, if we have a character χ on Σ[i1] given in advance, we shall speak of an [d1]action of Σ on $(\pi, ([L_i]))$ compatible with χ. If we are given an invertible $\mathbb{Z}$-module T, a T-loop structure on a group with loops π (with $\pi \neq 0$), endowed with an isomorphism $T \simeq T_\pi$, [d2]

We have profinite variants (or prime-to-p profinite ones, if p is a given prime…) — but already now there are two points to note, to be checked in this case:

$$\begin{cases} \mathrm{Norm}_\pi(L_i) = \mathrm{Centr}_\pi(L_i) = L_i \text{ in the case } \nu = 1, \text{ otherwise no problem} \\ \mathrm{Centr}(\pi) = (1) \quad \text{(anabelian case)} \end{cases}$$

more generally, the centralizer of every open subgroup of π is reduced to 1…[m246]

Marginal note. [m246] This is not proved for the moment in any profinite anabelian case!

[p. 58]

14. Cohomological digression (on the|the "plugging the holes).

Let X be a locally noetherian regular scheme of dimension 1, S a closed subscheme reduced discrete[i1] such that $\forall s \in S$, $\dim_s S = 1$ (so S defined by a closed discrete subset of X), $U = X \setminus S$. [m248]

Marginal note. [m248] It might perhaps be better to start with the purely topological case|the purely topological cases of a surface… and make the link with discrete groups.

We want to make explicit by Galoisian means the étale sheaves of sets[i2] constructible[i3] on X such that $F \mid U$ is locally constant. By the topos|carpet of Artin on the opens of the topos[i4], they correspond to triples

$$(F_U, F_S, \varphi)$$

where F_U is a constructible[i5] locally constant sheaf on U, F_S a sheaf (necessarily|necessarily locally constant) and φ a morphism

$$F_S \xrightarrow{\varphi} j^* i_*(F_U)$$

(where $i : U \hookrightarrow | \to X$ and $j : S \to X$ are the inclusions). Any constructibility condition being set aside, an étale sheaf F on X corresponds to such a triple — we restrict ourselves here to the F such that F_U [d1] comes from the fundamental topos $B_{\Pi_1(U)|\pi_1(U)}$ of U [d2]…(There is no need to assume F_U has finite fibers, 118

[scan 123]

[p. 60] where [d1] $\Pi_i = \mathrm{Ker}(\sigma_i)$ fits into the exact sequence

$$1 \longrightarrow \Pi_i \longrightarrow \mathcal{E}_i \longrightarrow \Gamma_i \longrightarrow 1$$

The case where the $E_i \longrightarrow E_U$ are isomorphisms, i.e. the E_i are identified|being identified [d2] all with E_U, with trivial action of|of the Π_i on E_U, corresponds to the case where F is essentially locally constant|constant on X, whence at once

$$\pi_1(X) = \mathcal{E} = \pi_1(U) \ / \ {}^{\text{normal subgroup generated}}_{\text{by the } \rho_i(\Pi_i)}.$$

Our aim is that of a Galois-theoretic calculation (if possible) of the cohomology of X for the F under consideration. Let $B_{X,U}$ be the topos whose sheaves are[i1] triples (F_U, F_D, φ) as above, which thus maps to the topos $B_{\pi_1,X}$, corresponding to the pairs for which φ is an isomorphism, and receives the topos $X_{\text{ét}}$:

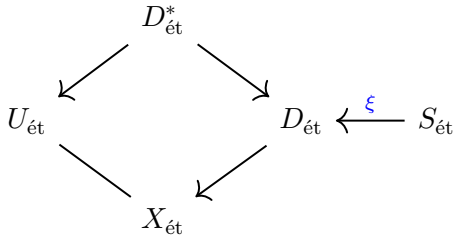
[p. 61] follow, corresponding to the [d1] case where the $D_s|O_s$ are gauges with residue field $k(s)$ of characteristic 0, we are going to suppose that

$$\Pi_i \simeq \widehat{\mathbb{Z}} \qquad \text{(not canonically)}$$



– in fact, by Kummer theory we have a system of Tate local systems $T_{\mathcal{E}}$ (on $\mathcal{E}$)[i1], T_i (on Γ_i)[i2], and $\mathcal{E}_i$-[i3]isomorphisms $T_{\mathcal{E}} \simeq T_i$, [d2] (i.e. a T_X on which $\widetilde{\mathcal{E}}|\overline{\mathcal{E}} = \mathcal{E}/\ldots$ operates) and we shall have a canonical Kummer isomorphism

$$T_i \xrightarrow[\sim]{\kappa_i|k_i} \Pi_i.$$

We would like to be able to paraphrase, on $B_{X,U}$, the well-known exact cohomology sequence

$$\longrightarrow H^i(X,F) \longrightarrow H^i(U,F) \longrightarrow H_S^{i+1}(X,F) \longrightarrow \cdots$$

relative to the open U of the topos X, and its closed "complement" S. Now, [d3] just as[i4] X fits into a diagram of topoi

[scan 129]

[p. 63] [d1] i.e. the topos B_{D,D^*} is equivalent to $D_{\text{ét}}$ – now the $H^i_S(X_{\text{ét}}, F)$ are indeed calculated on $D_{\text{ét}}$...We thus find

Proposition. The homomorphism of exact cohomology sequences under consideration is an isomorphism, provided we know that the homomorphism $H^i(\mathcal{E}, F_{\mathcal{E}}) \xrightarrow{\sim} H^i(U_{\text{ét}}, F_U)$ is an isomorphism for $\forall i$ (F_U an étale|étale local sheaf on $U_{\text{ét}}$ defined by a group $F_{\mathcal{E}}$ on which $\mathcal{E} = \pi_1(U)$ operates).

Example : OK[i1] If U is an affine curve over algebraically closed k F [d2] prime to characteristic[i2] (since OK for $i = 0, 1$, and for $i = 2$, the two sides are zero (the Galois cohomology|cohomology, since the fundamental group prime to p[i3] is [d3] free...) – whence we deduce the analogous case for $U|X$ affine over arbitrary k, then even if U is not affine but simply quasi-projective ? [d4] [m253]

Marginal note. [m253] Corollary. In this case, the cohomology of X with coefficients in a locally constant F_X is also calculated Galois-theoretically ? No, because of genus 0 !!! In the case of smooth projective curves of genus $\neq 0$ a special argument is needed.

We are now interested in the case where X projective (connected)[i4] over algebraically closed k, we thus see|we thus know

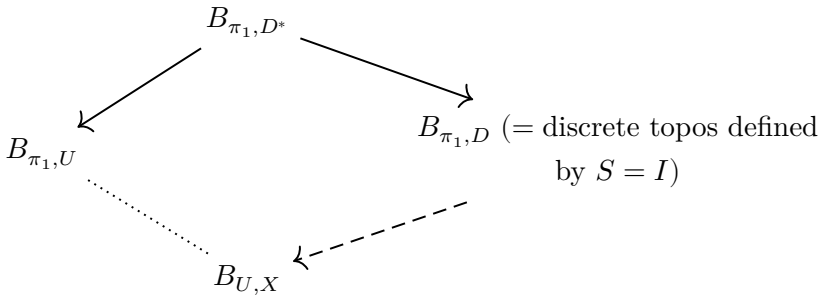
that : d1 a) If $S = \emptyset$ i.e. $X = U$, the cohomology of U with (coefficients in local systems) is that of π. Thus…a canonical isomorphism



$$H^2(\pi, T) \simeq H^2(X, T) \quad (\simeq \widehat{\mathbb{Z}})$$

m254

Marginal note. m254 with grain|grains of salt in characteristic $p > 0$

d2

b) If $S \neq \emptyset$, the $H^i_!(U, -)$ are determined|described and calculated by Galois-theoretic means, in terms of the d3 groups[i1] with loops, making it possible to reconstruct the situation

by postulating that the component B_{π_1, D_i^*} is none other than B_{L_i} (with the notations of the preceding number^o|case). We then find canonical isomorphisms (by local calculations)

$$H^2_{S_i|s_i}(B_{U,X}, L_i) \simeq \widehat{\mathbb{Z}} \quad \text{i.e.} \quad H^2_{S_i|s_i}(B_{U,X}, \widehat{\mathbb{Z}}) \simeq L_i^{\otimes -1}$$

(if $g \neq 0$)

$$H^2_{S_i|s_i}(B_{U,X}, \widehat{\mathbb{Z}}) \xrightarrow{\sim} H^2(X, \widehat{\mathbb{Z}}) \simeq H^2(\pi, \widehat{\mathbb{Z}})$$

whence in [d4] putting together, canonical isomorphisms

$$L_i \simeq H^2(\pi, \widehat{\mathbb{Z}})^{\otimes -1}.$$

m255

Marginal note. [m255] But in all cases (even if $g = 0$, so long as we do not have $\nu = 0$) [d6] we find $H^2_!(B_{\pi_1,U}, \widehat{\mathbb{Z}}) \simeq \widehat{T}_\pi^{\otimes -1} | T_\pi^{\otimes -1}$ canonically, whence a cohomological description of the orientation modules, common to the case without holes and with holes…

Scans 131–140

[scan 131]

[p. 64]

We find that the composites

$$T_\pi \xrightarrow{\sim} L_i \longrightarrow H^2(\pi, \widehat{\mathbb{Z}})^{\otimes -1}$$

do not depend on the choice of i, so that the orientation module T_π of the group profinite π^{i1} with loops π is identified with the dual of $H^2(\pi, \widehat{\mathbb{Z}})$ (if $g \neq 0$).

Let us now consider a homomorphism of groups with loops

$$\pi' \xrightarrow{f} \pi$$
$$I'_0 \xrightarrow{\tau} I$$

associated with an isomorphism $T_{\pi'} \simeq T_\pi$ and a degree map $d : I'_0 \longrightarrow \mathbb{N}$ [d1] (N.B. $i' \in I' \setminus I'_0 \longrightarrow f(L'_{i'}) = (1)$.

We would like to deduce from this a diagram of morphisms of topoi

$$\begin{array}{ccccc} B_{\Pi_1 U'} & \longrightarrow & B_{X',U'} & \longrightarrow & B_{\Pi_1 X'} \\ \downarrow & & \downarrow & & \downarrow \\ B_{\Pi_1 U} & \longrightarrow & B_{X,U} & \longrightarrow & B_{\Pi_1 X} \end{array}$$

and a homomorphism trace on the cohomology with proper supports of U', U (defined in terms of cohomology on $B_{X',U'}, B_{X,U}$ relatively) [d4] inducing [d5] an isomorphism

$$H^2_!(U', \widehat{\mathbb{Z}}) \longrightarrow H^2_!(U, \widehat{\mathbb{Z}})$$

When we give ourselves a group of operators [d1]Γ on the situation $(X', S') \longrightarrow (X, S)$ hence on the groupoidal or topossic situation, we must take this into account in the description above. Thus I'_0 and I'_1 are stable under Γ, and the morphism [d2] $B_{D'_1} \longrightarrow B_U$ must be stable under Γ. [d3] [d4] Which also means, probably, that we have a morphism of topoi from $B_{D'_1,\Sigma} = B_{I'_1,\Sigma|\Gamma}$ into $B_{U,\Gamma}$. Choosing for every orbit of Γ in I'_1 a representative $s' \in I'_1$, and considering its stabilizer $\Gamma_{s'} \subset \Gamma$, we must therefore for every such orbit i.e. [d7] every i' give ourselves a $\Gamma_{s'}$-object of the category of universal coverings of (U, Γ). [p. 69]

i.e. set|to the of liftings of $\Gamma \longrightarrow \mathrm{Autext}\,\pi$ to[i1] $\Gamma \longrightarrow \mathrm{Aut}(\pi)$, modulo π-conjugation.
Question (If $\Gamma^0 \neq (1)$)[i2] Is this map bijective ??

[If $\Gamma^0 = \{1\}$, $\Gamma/\Gamma^0 \simeq \{\pm 1\}$, then X^Γ is the set of real points of a real algebraic curve and $U^\Gamma = X^\Gamma - S^\Gamma$ is the complement of a finite subset in it, we have

$$\pi_0(X^\Gamma - S^\Gamma) \longrightarrow \pi\text{-classes of splittings of } \mathcal{E} \text{ over } \Gamma$$

and the [d1] analogous question of bijectivity arises, for extensions of ± 1 by π...]

For the injectivity of the map in the case $\Gamma^0 \neq (1)$, we may suppose $\Gamma = \Gamma^0_a|\Gamma^0 \simeq \mathbb{Z}/p\mathbb{Z}$, with p prime, i.e. Γ generated by a complex automorphism $\gamma|y$[i3] of order p, which defines (if $x, y \in U^\Gamma$, $x \neq y$) an automorphism of order p of $\pi_1(U, x)$, [d2] u_x, that is [d3] (hence π-conjugacy class of automorphisms of π of order p), and another u_y. We have to prove that u_x, u_y are not conjugate under π

[scan 140]

Theorem Let $U|X$ be [d1] a connected topological space[i1] ([d2], by paths)[i2], Γ a finite group operating [d3] on U, $\widetilde{U}$ a universal covering of U, hence [d4] an extension group

$$1 \longrightarrow \pi \xrightarrow{i} \mathcal{E} \xrightarrow{p} \Gamma \longrightarrow 1$$

operating faithfully on $\widetilde{U}$ ($\pi = \mathrm{Aut}_U(\widetilde{U}) \simeq \pi_1(U)$...). For every fixed point $x \in U^\Gamma$, Γ operates on the universal covering punctured|pointed over x, say [d5] $R_x|\mathcal{R}_x$, leaving fixed the point marked[i3] $\tilde{x}$ of R_x over x, hence a splitting of the extension relative to R_x

$$1 \longrightarrow \pi_x \xrightarrow{i_x} \mathcal{E}_x \underset{\sigma_x}{\overset{p_x}{\rightleftarrows}} \Gamma \longrightarrow 1$$

and for every [d6] isomorphism[i4] ℓ ("path")[i5] $R_x \simeq \widetilde{U}$, inducing an isomorphism of extensions $\mathcal{E}_x \xrightarrow{\sim} \mathcal{E}$ (defined of|in modulo composition with an inner automorphism induced by an $\alpha \in \pi$...) we find by transport of structure a splitting $\sigma_{x,\ell}$ of $\mathcal{E} \xrightarrow{p} \Gamma$, (which, for varying ℓ, is defined up to an inner automorphism by an $\alpha \in \pi$). We thus find a map

$$(*) \quad U^\Gamma \longrightarrow \begin{array}{c} \text{classes of } \pi\text{-conjugacy of splittings} \\ \text{of the extension } \mathcal{E} \text{ of } \Gamma \text{ by } \pi \\ = \text{classes of } \pi\text{-conjugacy of subgroups } \textit{sections } \Gamma' \text{ of } \mathcal{E} \end{array}$$

[scan 141]

[p. 70]

The image of this map thus consists of the π-conjugacy classes of the[i1] section subgroups $\Gamma' \subset \mathcal{E}$ such that $\widetilde{U}^{\Gamma'} \neq \emptyset$, and for such a Γ', the set of $x \in U^{\Gamma}$ which [d1] give as image this conjugacy class is the image of $U^{\Gamma'}$ in U. Finally, if x is in this image, the set $\widetilde{U}_x^{\Gamma'}$[i2] of the $\tilde{x} \in \widetilde{U}^{\Gamma'}$ over x ([d2] hypothesis on a|x) is a torsor under $\pi^{\Gamma'}$ i.e. if $\tilde{x} \in (\widetilde{U}^{\Gamma'})_x$, [d3] and if $\alpha \in \pi$, then

$$\alpha.\tilde{x} \in \widetilde{U}^{\Gamma'} \quad \Longleftrightarrow \quad \alpha \in \pi^{\Gamma'}$$

(Trivial verification, as for that matter all the preceding assertions). Thus, the following conditions are equivalent:

m262

Marginal note. [m262] N.B. $\widetilde{U}_x$ being identified with $\mathrm{Isom}_U(R_x, \widetilde{U})$, $\widetilde{U}_x^{\Gamma'}$ is identified with $\mathrm{Isom}_{U,\Gamma}(R_x, \widetilde{U}_{\Gamma'})$ of the two isomorphisms that commute|of covering isomorphisms commuting with the action of Γ and $\pi^{\Gamma} = (1)$ means that this isomorphism is unique i.e. [d4] the conjugacy class of the sections [illeg. 2].

a) $(*)$ is a bijection, and $\forall$ subgroup Γ' of $\mathcal{E}$ a section of the extension, [d5] we have $\pi^{\Gamma'} = \{1\}$.

b) $\forall\, \Gamma'$ as in a), Γ' operating on $\widetilde{U}$ has a fixed poin[t] and only one.

This being so, let us prove the

Fundamental lemma Let Γ be a finite[i3] finite group, operating faithfully on a space[i4] $D \simeq \mathbb{R}^2$, let [d6] Γ° be the subgroup of Γ

d1

d2

d3

a) Suppose first that one can find a C^2 structure on D invariant under Γ — then a standard argument shows that there exists a conformal structure invariant under Γ, now the fundamental theorem of conformal mapping shows that then

either $D \simeq$ interior Δ of the unit disk Δ or of the Poincaré half-plane
or $D \simeq \mathbb{C}$ (conformal isomorphisms).

In the first case, the group of conformal automorphisms [d4] is

$$\simeq \mathrm{Sl}(2,\mathbb{R})^{\sim} \mid \mathrm{Gl}(2,\mathbb{R})^{\sim} = \{u \in \mathrm{Gl}(2,\mathbb{R}) \mid \det u = \pm 1\}$$

([d5] $u = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ operating on [d6] $\widehat{\mathbb{C}}$[i3] by [d7] $\Theta_u \circ \tau^{\det u}$, where τ is complex conjugation and $\Theta_u(z) = \dfrac{az+b}{cz+d}$, and leaving the Poincaré half-plane stable), and every compact subgroup is contained in a[i4] conjugate of the maximal compact subgroup, which (on passing back to the unit disk Δ[i5]) is identified with the group $O(2,\mathbb{R})$ of

transformations of the unit disk of the form

$$z \longrightarrow \zeta\tau^{\varepsilon}(z) \qquad \begin{array}{c} \zeta \in \mathbb{U} = \{\zeta \in \mathbb{C} \mid |\zeta| = 1\} \\ \varepsilon \in \{\pm 1\} \\ \tau \text{ complex conjugation} \end{array}$$

Every finite subgroup of this group is of one of the types made explicit above — we win, by using a homeomorphism $[0,1[\longrightarrow [0,+\infty[$ to define a homeomorphism [d1] $\Delta \simeq \mathbb{C}$ commuting with the action of $G = O(2,\mathbb{R})$.

In the case $D \simeq \mathbb{C}$, we see that [d3] the group of conformal automorphisms of $\mathbb{C}$ is the group of transformations $az+b$ or $a\overline{z}+b$, in which a maximal compact subgroup is the same group $O(2,\mathbb{R})$ as just now — and every compact subgroup (a fortiori, every finite subgroup) is contained in a conjugate of this one. We win again.

The rest of the work consists essential[lyi1] in [d5] showing that the hypothesis of non-wildness

[p. 72]

is always satisfied, at least for Γ°. Suppose first $\Gamma = \Gamma^\circ$.[i1] [d1] We assume[i2] that all is proved for [d2] the orders[i3] $<$ card(Γ). [d3]

b) Γ has a fixed poin^{t} $o|0$[i4], i.e. $D^\Gamma \neq \emptyset$.

Otherwise, the stabilizer subgroups Γ_x[i5] of the $x \in D$ being of order $<$ [d4] card Γ, by the induction hypothesis, the Γ_x have the structure stated in the theorem, hence $D^\Gamma = U|D/\Gamma = U$ is a topological surface and $D \longrightarrow U|D \longrightarrow D^\Gamma$ is a ramified covering, let us choose a [d5] conformal[i6] structure on U [d6]; there is a unique conformal structure on D such that $D \longrightarrow U$ is [d7] "conformal"[i7] (holomorphic or anti-holomorphic), this is invariant under Γ, and by a) Γ has a fixed poin^{t}, contradiction.

c) Γ has no fixed poin^{t} other than $o|0$. We let Γ operate faithful[lyi8] on $D^* = D \setminus \{o\}|D^* = D \setminus \{0\}$, and we have to prove that $D^{*\Gamma} = \emptyset$.

Let then $x \in D^{*\Gamma}$ — we are going to reach a contradiction. Consider the universal covering $\widetilde{D}^*$ of D^* pointed at x, [d1] so Γ operates on $\widetilde{D}^*$ with a fixed poin^t $\tilde{x}$ over x. Here $\pi = \pi_1(D^*) \simeq \mathbb{Z}$, and Γ operates on it trivial^{ly} (since $\Gamma = \Gamma^\circ$) so $\Gamma \times \mathbb{Z}$ operates on $\widetilde{D}^*$. We may assume $D = \mathbb{C}$, $o = 0|0 = 0$, $x = 1$, $D^* = \mathbb{C}^*$, $\widetilde{D}^* = \mathbb{C}$, $\tilde{x} = 0$, $\widetilde{D}^* \longrightarrow \widetilde{D}$ given by $\exp 2i\pi z$, [d2] and $\mathbb{Z}$ operating on $\mathbb{C}$ by $\Theta_n z = z + n$ $(n \in \mathbb{Z})$.

[d3] It remains to prove that if a finite group^{i1} Γ operates on $\mathbb{C}$ commuting [d4] with the action of $\mathbb{Z}$ on $\mathbb{C}$, and leaving [d5] fixed the poin^t $o|0$, then Γ operates trivially (which contradicts the hypothesis of faithfulness of the operation).

[d6] We are reduced to the.

commuting with $z \longmapsto z+1$, and leaving the origin invariant. Then $u = \mathrm{id}$

We may assume ^{d1} $\exists$ prime number p such that $u^p = \mathrm{id}$, i.e. that u corresponds to an operation of $\Gamma = \mathbb{Z}/p\mathbb{Z}$ on $\mathbb{C}$. All the poin^{ts} of $\mathbb{Z} \subset \mathbb{C}$ are fixed by Γ.^{i1} Passing to $\widehat{\mathbb{C}} \simeq S^2$, we find that ∞ is an accumulation poin^{t} of the fixed poin^{ts} under Γ — if Γ did not operate trivially, this would be decidedly very wild! We ought to be able to finish by the Adams spectral sequence... I am not going into these mazes...

d) The purely topological part being admitted|thus assumed|assumed proved|proved, we thus conclude from this, if $\Gamma \neq \Gamma^\circ$, $\Gamma^\circ \neq (1)$, ^{d2} as^{i2} ^{d3} $D^{\Gamma^\circ i3}$ is invariant under Γ, ^{d4} as^{i4} D^{Γ° is reduced to a poin^{t}, this one is invariant under all of Γ, not just Γ°. On the other hand, We know enough now to know that if Γ finite group operates on a surface ^{d5} paracompact U^{i5}, the Γ_x ($x \in U$) respecting the orientation, then $U/\Gamma = V$

is a surface — and $U \longrightarrow V = U/\Gamma$ is a ramified covering[i1] and choosing a conformal structure on this one, we find by inverse image a conformal structure on U invariant under Γ, [d1] For the case $U = D$[i2] we finish by a), [d2] for the complement to the fundamental lemma. [But to do things properly, one would have to prove that there always exists invariant conformal structure, [d3] Γ finite group operates on surfaces [d4] paracompact — so U/Γ is a surface with boundary.... Here what is missing is the analysis of the action of an anti-involution of a surface in a neighborhood of a fixed poin^{t}...]

m263

Marginal note. [m263] One would have to prove that if τ is an involutive anti-automorphism of D, then $\exists$ isomorphism $D \simeq \mathbb{C}$ such that τ becomes $z \longmapsto \overline{z}$ (hence $D^\tau \simeq \mathbb{R}$!) which should make it possible to prove, if $\Gamma \simeq \mathbb{Z}/2\mathbb{Z}$ operates by anti-automorphisms on U (oriented|orientable $U \neq S^2$) that $\pi_0(U^\Gamma) \Longrightarrow \pi$-conjugacy classes of sections of $\mathcal{E}$ over Γ is bijective.

Consequence of the fundamental lemma:

Theorem. Let U be a paracompact topological surface 0-connected[i3], Γ a finite group operating faithfully on U, we assume $\widetilde{U}$ [d5] noncompact (i.e. U not homeomorphic to S^2 nor

[p. 74]

to the real projective plane), we assume that [d1] that moreover[i1] if U is [d2] orientable, then [d3] [d4] assume that the subgroup Γ° of Γ of the $g \in \Gamma$ which preserve an orientation is $\neq (1)$ [hence Γ not reduced either to 1, or to 1 and|Id an anti-involution], and if U nonorientable, that [d5] $\Gamma \not\simeq | \neq (1), \{\pm 1\}$ i.e. $\operatorname{card}\Gamma \geq 3$. This being so, [d6] let us consider [d7] the extension[i2] $\mathcal{E}$ of Γ by $\pi = \pi_1(U)$, and the map

$$U^\Gamma \longrightarrow \begin{array}{c}\text{Classes of } \pi\text{-conjugacy of} \\ \text{splittings of } \mathcal{E} \longrightarrow \Gamma\end{array}$$

we have this:

a) This map is bijective

b) For every section subgroup $\Gamma' \subset \mathcal{E}$, we have $\pi^{\Gamma'} = (1)$

c) If $U^\Gamma \neq \emptyset$ i.e. If there exists a splitting, then Γ is cyclic or dihedral (and in the case U oriented, Γ° is cyclic)

N.B. The hypotheses on U ensure that $\widetilde{U} \simeq D$, and those on Γ that Γ operating on D satisfies the hypotheses of the fundamental lemma.

Scans 151–160

[scan 151]

[p. 75]

Let us prove a). Let $\Gamma' \subset \mathcal{E}$ be a partial section over Γ_x [i1] deduced from $x \in U^!$. Let $\Gamma'' \supset \Gamma'_x$ be another subgroup|subgroup let $\Gamma_1 \supset \Gamma_x$ be its image in|of Γ[i2] such that $\Gamma'' \cap \pi = (1)$ i.e. $\Gamma'' \hookrightarrow \Gamma$ [illeg. 1][i3]. By the preceding theorem, it is defined by a unique $y \in U^{\Gamma_1} | y \in U^{\Gamma''_*}$, and it is clear that this y does not change if we replace the action of Γ_1 on U by the action of a smaller group $\neq (1)$ (and the induced section) such as Γ_x, hence Γ_1 [d1] fixes x hence (by definition of Γ_x) $\Gamma_1 = \Gamma_x$ hence $\Gamma'' = \Gamma'$, [d2]

[d3]b)[i4] Let x, y give the same image $[\Gamma']$ $[\Gamma'']$, hence $\Gamma_x = \Gamma_y$, say Γ_1, and applying the theorem to Γ_1 operating on U, we find $x = y$. Let, on the other hand, Γ'_0 be a maximal partial section $\neq 1$, $\Gamma_0 \subset \Gamma$ its image, by the theorem applied to the action of Γ_0 on U,[i5] $\exists x \in U$ [d4] such that $x \in U^{\Gamma'_0}$ i.e. $\Gamma'_0 \subset \Gamma_x$, and such that $[\Gamma'_0]$ is defined by x, but if $[\Gamma']$ is defined by x for the action of Γ_x in its entirety, we will have $[\Gamma'_0] \subset [\Gamma']$, hence by the maximal character of $[\Gamma'_0]$, we will have $[\Gamma'_0] = [\Gamma']$, which [d5] proves b). On the other hand c) is clear. 150

[scan 152]

Let us now return to the case where $U = X \setminus S$, X a compact T-oriented surface and S a finite subset, anabelian case — so we have a "fully[i1] faithful" description of U by a π with loop structure, and we would like to convince ourselves that [d1] the outer[i2] operation of Γ on π, when Γ preserves orientation (to simplify) also suffices to describe fully the object (U, Γ) in the appropriate isotopic category. [m266]

Marginal note. [m266] we should return to the general case for what follows…

We already recover a description of $U^!$ in terms of the action of π, let J $(\simeq U^!)$[i3], the set of π-conjugacy classes [d2] of maximal partial sections $\neq 1$[i4] of $\mathcal{E}$ over Γ, For every $j \in J$, j is a π-[i5]torsor as a π-[i6]conjugacy class of sections [that it is a π-torsor follows from $\pi^{\Gamma'} = (1)$, a priori [d3] the stabilizer|the stabilizers of Γ'[i7] is precisely $\pi^{\Gamma'}$] In fact, 151

[p. 76]

the set of all these [d1] maximal partial sections is naturally an $\mathcal{E}$-set (by conjugation) [d2] on which π operates freely, and this $\mathcal{E}$-set is canonically identified with $\widetilde{U}|U^! = \widetilde{U}^!$, for the structure of $\mathcal{E}$-sets.

Let $S' = S \cup U^!$, hence $U' = X \setminus S'$, we must try to reconstruct (in terms of the extension $\mathcal{E}$ of Γ by the group with loops π) the outer[i1] group with loops corresponding to X', S' i.e. to U', and the [d3] outer action[i2] of Γ on it. [d4] [d5]

But first we should make sure of the intrinsic character of the definition of J $(\simeq U^!)|(\simeq \widetilde{U}^!)$ as a Γ-set,[i3] in terms of the [d6] [d7] outer group π, and of the outer action [d8] of Γ on it. 152

[scan 154]

This is rather obvious moreover (in terms precisely[i1] of the π-[i2]conjugacy classes of partial liftings of $\Gamma \to \mathrm{Autext}(\pi)$ to $\mathrm{Aut}(\pi)$), we would however also like an intrinsic description of $\widetilde{U}|U^!$, in|or a paradigm for the map of Γ-spaces $U^! \longrightarrow U$ we must therefore describe a morphism of topoi with operation of Γ on it

$$B_J \xrightarrow{\rho} B_{\mathcal{E}}$$

which therefore corresponds to an [d1] "inverse image" functor $\rho^*|?^*$ (compatible with action of Γ) [d2]

$$\begin{array}{ccc} B_{\mathcal{E}} & \longrightarrow & B_J \\ \wr\| & & \wr\| \\ \pi\text{-Sets} & & \text{Ens. over } J \end{array}$$

This [d3] is nothing other than the contracted product over π with the set of maximal partial sections $\neq 1$ of $\mathcal{E}$ over Γ 153

[p. 77]

Let us return to the extension $\mathcal{E}$ of Γ by π [d1] arising from a geometric situation (which extension, in the anabelian case, is already defined in terms of an outer operation of Γ on π) we know that it satisfies additional draconian conditions! [d2] (To formulate them, we will assume the action of Γ faithful):[i1] every subgroup $\Gamma' \subset \mathcal{E}$ such that $\Gamma' \cap \pi = (e)$ ("partial section") is cyclic (if $\Gamma' = \Gamma'^0$) or[i2] [d3] dihedral, (if $\Gamma' \neq \Gamma'^0$)[i3] and the set of π-conjugacy classes of such subgroups is finite. Every section subgroup $\Gamma' \neq 1$ is contained in a unique section[i4] subgroup that is maximal. [m270]

Marginal note. m270 good|so

(We have established it at least in the case $\Gamma = \Gamma^0$, we should return to the general case, I think it remains true as it stands, to be checked…) m271

Marginal note. m271

[A vertical stroke to the left of the two lines "I think … checked…)".]

Moreover, we saw an additional structure appear on the group $\mathcal{E}$ [which in the anabelian case is identified with a subgroup of $\mathrm{Aut}(\pi)$], namely a map

$$\mu_{\mathcal{E}} : \text{elements } u \text{ of finite order in } \mathcal{E} \longrightarrow T \otimes \mathbb{Q}/\mathbb{Z},$$

obtained by noting that if $u \in \mathcal{E}$ is of finite order n, whence $\mathbb{Z}/n\mathbb{Z} \underset{i}{\hookrightarrow} \mathcal{E}$, we have|i.e. $\mathrm{Im}\, i \cap \pi = (1)$ (π has no torsion elements), hence $\mathbb{Z}/n\mathbb{Z} \hookrightarrow \Gamma$, whence|of a subgroup $\Gamma_1 \subset \Gamma$ (i.e. the image of m272

Marginal note. m272 N.B. For a u of finite order in $\mathcal{E}$, we must know|have, if $u \notin \mathcal{E}^0$, that u is of order 2 exactly, [illeg. 5] to define $\mu(u)$!

u in Γ has the same order n), and the lifting $\Gamma_1 \hookrightarrow \mathcal{E}$ defines an $x \in U^{\Gamma_1}$, [d1] and u_1 operating on U while leaving x fixed therefore corresponds in a neighborhood of x to a "multiplier", which (for a chosen local orientation) is a primitive nth root of 1 i.e. an element of $\mathbb{Z}/n\mathbb{Z}$, and which for varying orientation is interpreted intrinsically as an element of $T \otimes \mathbb{Z}/n\mathbb{Z} \subset T \otimes \mathbb{Q}/\mathbb{Z}$.

The map μ satisfies the obvious conditions

$$\begin{cases} \mu(\alpha u \alpha^{-1}) = \mu(u) & \text{if } \alpha \in \pi \\ \mu(u^n) = n\mu(u) & \text{if } n \in \mathbb{Z} \end{cases}$$

$$\text{order } \mu(u) = \text{order of } u$$

I do not know whether this map μ [d2] can be[i1] defined intrinsically in terms of the extension $\mathcal{E}$, or whether on the contrary there can exist two extensions [d3] $\mathcal{E}, \mathcal{E}'$ of Γ by π, defined by geometric situations, of Γ operating on U resp. U', and an isomorphism of extensions $\mathcal{E} \longrightarrow \mathcal{E}'$ which is not compatible with the functions μ, μ'. The simplest nontrivial case to look at is the 155

[p. 78]

abelian case (where $\pi \simeq \mathbb{Z}$ [d1] (card $I = 2$)[i1] or $\pi \simeq \mathbb{Z}^2$ ([d2] $I = \emptyset$)), In the first[i2] case [d3] $\pi \simeq \mathbb{Z}$, we|†[d4] must have (to have a faithful action of $\Gamma = \Gamma^0$)[i3] [d5] Γ^0 cyclic, $\mathcal{E} \simeq \mathbb{Z}$, there is no element of finite order in $\mathcal{E}$ except 1|e, so the question does not arise. The case $\pi \simeq \mathbb{Z}^2$ is more interesting, [d6]

If π is a free $\mathbb{Z}$-module of [d7]rank n[i4], we have an exact sequence

$$0 \to \pi \to \pi \otimes_{\mathbb{Z}} \mathbb{R} \longrightarrow X_0(\pi) \longrightarrow 0$$

Torus of dimension n associated to π

and if Γ operates on π, the cohomology exact sequence (taking into account $H^i(\Gamma, \pi \otimes_{\mathbb{Z}} \mathbb{R}) = 0$ for $i > 0$) gives

$$H^2(\Gamma, \pi) \xleftarrow{\sim} H^1(\Gamma, X_0(\pi))$$

extension class|extension classes of Γ by π

classes of $X_0(\pi)$ torsors, with operation of Γ on them compatible with its action on $X_0(\pi)$

thus the datum of an extension $\mathcal{E}$ of Γ by π amounts essentially to that of a Γ-$X_0(\pi)$-torsor X (inhomogeneous n-torus on which Γ operates — hence it operates on its group of translations X_0, hence on $\pi = \pi_1(X_0, 0)$…). If it were true for $n = 2$[i5] that every operation 156

[scan 158]

of Γ on a toroidal surface ($\simeq S^1 \times S^1$) is isomorphic to such a standard action, then the intrinsic character of the map μ in this case would be established — which would not for all that make the computation of μ uninteresting, which takes its values in $T \otimes \mathbb{Q}/\mathbb{Z}$, where here

$$T \simeq \bigwedge\nolimits^2_{\mathbb{Z}} \pi \quad (\text{dual|dimension 2 of } H^2(\pi, \mathbb{Z}) \simeq \bigwedge\nolimits^2 \underbrace{H^1(\pi, \mathbb{Z})}_{\downarrow\wr \simeq \ \pi^\vee}).$$

The question comes down to this: We have a split extension of a cyclic [d1]group[i1] $\mathbb{Z}/n\mathbb{Z}$ with generator u by π — thus described entirely by an automorphism [d2] θ of π such that $\theta^n = \mathrm{id}_\pi$), describe in terms of this an element of $T \otimes \mathbb{Q}/\mathbb{Z}$.

Answer: the standard|standard of which geometric situation corresponds to $X = X_0(\pi)$, with 0 as a fixed point under Γ. If u reverses orientation, it is of order 1 or|i.e. 2, there is no problem, otherwise it is [d3] in $\pi \otimes_{\mathbb{Z}} \mathbb{R}$ a rotation around 0 (of order $2, 3, 4$ or 6) which is readily specified by an element of [d4] $T \otimes \mathbb{Z}/\nu\mathbb{Z}$ (if ν is of order|the order). It is also (if we identify $T \otimes \mathbb{Z}/\nu\mathbb{Z}$ with $\mu_\nu(\mathbb{C}^*)$, assuming $T \simeq \mathbb{Z}$ given i.e. π oriented i.e. $X_0(\pi) = X$ oriented) one of the two 157

[p. 79]

eigenvalues of $u \otimes_{\mathbb{Z}} \mathbb{C}$ (automorphism of the vector space over $\mathbb{C}$ of dimension 2 $\pi \otimes_{\mathbb{Z}} \mathbb{C}$).

This shows us, in the case of algebraic geometry over an algebraically closed field Ω, that if $X = X_0$ is an elliptic curve u an automorphism of finite order, we have as a paradigmatic description not only $\pi = \pi_1(X, 0)$ ($\widehat{\mathbb{Z}}$-module free of rank 2),[i1] (and the action of u on π), but as an additional structure one of the two solutions in Ω of the characteristic equation of u (with integer coefficients)

$$T^2 + aT + b = 0 \qquad (a = -\operatorname{Tr} u,\ b = \det u).$$

It is clear that this additional structure cannot be deduced from knowledge of the action of u on π alone. [m277]

Marginal note. [m277]

for $\Omega = \mathbb{C}$ [illeg. 2] comes down to [illeg. 1] orientation|orientations of [illeg. 1]

But there remains the question whether this [d1] $\mu(u) \in \mu_n^*(\Omega)$[i2] can be deduced from knowledge at least of the outer[i3] action of u on the group "with 1 loop" corresponding to the geometric situation — i.e. an outer[i4] automorphism [d2] of order n of such a group (or whether here again one must decidedly regard it as an additional datum). [m278]

Marginal note. m278 yes, it can, thanks to the consideration of the "subgroups [illeg. 2] of $\mathcal{E}$" [illeg. 2] which define extensions

$$1 \longrightarrow T \longrightarrow \mathcal{E}_i \longrightarrow \Gamma_i \longrightarrow 1$$
$$\qquad\qquad \searrow^{n_i \mathrm{id}_T} \wr$$
$$\qquad\qquad\qquad T$$

whence $\Gamma_i \simeq T/n_i T$ [illeg. 2]

But if this were indeed so, it would imply on the other hand that the construction of $u \in$ group|these groups with 158

[scan 160]

(1) loop(s), with the operation of Γ on it, cannot be carried out either with the help of the mere d1 knowledge of the action of Γ ($= \mathbb{Z}/n\mathbb{Z}$) on π. It is this question of "drilling holes" that we must therefore in the end, at the very end, tackle!

As for the question of whether d2in i1 d3 the anabelian case, the map

$$\mu : \underbrace{\infty\mathcal{E}}_{\substack{\text{set of}\\ \text{elements}\\ \text{of finite order in } \mathcal{E}}} \longrightarrow T \otimes \mathbb{Q}/\mathbb{Z})$$

is deducible from the action of Γ on π [if it is faithful, $\mathcal{E}$ is thus identified with a subgroup of $\mathrm{Autext}_{\ell|l}(\pi)$ and we may ask whether μ is not i2then definable on this in its entirety], or it is|whether it is an additional datum one must have in order to reconstruct the geometric situation — the question remains entirely open. m280

Marginal note. m280 this does indeed seem so, taking into account [illeg. 1] that for Γ solvable, [illeg. 3], we know [illeg. 1] that every action d4 of Γ on π [illeg. 3] realize geometrically

[scan 165]

[p. 82] (when we start from X, S) fits into a triangle of morphisms of topoi

m284

Marginal note. m284 N.B. in the geometric case, d1 three topoi of this diagram are étale topoi ($D^*_{\text{ét}}, D_{\text{ét}}, S_{\text{ét}}$) and the arrows φ_D and ψ_D correspond to morphisms but not [illeg. 1] of topoi)

α_D, like α_X above, is just a plain homomorphism (not an isomorphism in general).

d2 When we speak of the canonical morphism from B_{D^*} to $B_{D;S}$ it is of[i1] φ_D (and not of $\psi_D\sigma$) that we are speaking — in the geometric case we have $B_{D^*} \simeq D^*_{\text{ét}}$, and φ_D corresponds to the inclusion of schemes

$$D^* \supset | = D \setminus S \longrightarrow D$$

and $\psi_D : B_S \longrightarrow B_{D;S}$ to the inclusion of schemes $S \longrightarrow D$[i2] whereas neither σ nor $\psi_D\sigma$ correspond in general to morphisms of schemes.

We thus obtain a diagram of topoi d3 [p. 164]

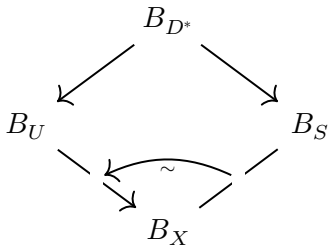
(**)



m285

Marginal note. m285 Careful, the triangle is not essentially commutative, but we have pseudo-commutativity…

where the three underlined topoi $\underline{B}_U$, $\underline{B}_S$ and $\underline{B}_{D^*}$ are multi-Galois, and $B_{D;S}$ and $B_{X;S}$ are composite (obtained by gluing two multi-Galois topoi). Unless I am mistaken the two squares are [not only essentially^t commutative but also] 2-cartesian (in the 2-category of topoi).[i1]

Passing to the B_{Π_1}? of the topoi considered (corresponding to the locally constant objects on these topoi) we find a topos[i2] $B_X = B_{\Pi_1 B_{X,S}} | B_{\Pi_1 B_{X;S}}$[i3] as an amalgamated sum of topoi in the [d2] diagram

(this square is indeed essentially commutative) and in the same way (replacing B_U by B_{D^*}) a B_D, which is however (via $B_S \longrightarrow B_D$) isomorphic (rather: equivalent|equal)[i4] to B_S. The diagram $(**)$ then becomes [p. 165]

where all the arrows except $D^*_{ét} \longrightarrow S_{ét}$ are induced by morphisms of topoi. Here $(***)$ maps to the corresponding diagram $(**)$, inducing isomorphisms of topoi for D^*, D, S, and for $U_{ét} \longrightarrow B_U$ and $X_{ét} \longrightarrow X$ inducing morphisms which have less tendency to be acyclic, but which are [d1] all the same in important cases, recalled in an earlier section…

The constructions of $(**)$ and $(***)$ in terms of the starting diagram

are purely formal, and independent of every hypothesis. The construction of a multi-Galois B_X, as an amalgamated sum, can be interpreted as the translation (at the level of fundamental groupoids) of an operation of "plugging holes". [d3] In the computational context [p. 167]

140-2-s171-D001 *deletion. Manuscript:* Critique of the notations. Whereas the letters graphic forms B_U, B_X are constructed in terms of the letters U, X (suggesting|being concerned with, in this instance|the origin, the schemes U, X) in the same way, they have quite different meanings — B_U denotes the classifying topos $B_{\Pi_1|\pi_1,U}$, but B_X a distinctly bigger topos. So I prefer to write [illeg. 1] finally $B_{X;S}$ (to suggest the sheaves on X set|essentially constant on $X \setminus S$ and on S) or better, $B_{U,S}$ (to suggest a topos obtained by gluing U and S, likewise B and likewise $B_{D;S}$; on the other hand in $B_{\Pi_1|\pi_1,D}$ and $B_{\Pi_1|\pi_1,X}$ one would write simply (as for B_U) B_D, B_X

[scan 172]

that we start simply with a morphism of multi-Galois topoi

$$B_{D^*} \longrightarrow B_U$$

but where in addition we have a group Γ (discrete, say — or profinite in the arithmetic context)[i1] which operates on B_{D^*}, B_U ; the preceding morphism commuting with the action of Γ.

Let us note that the datum of an action of Γ on a topos B makes it possible to construct a topos (B, Γ), and a morphism $(B, \Gamma) \longrightarrow B_\Gamma$ (classifying topos of Γ[i2] i.e. a Γ-torsor of (B, Γ) — and

B identifies with the topos induced by $\mathcal{X} = (B/\Gamma)$ on this Γ torsor. Conversely, the datum of a topos $\mathcal{X}$ and of a Γ-torsor U of $\mathcal{X}$, and of an isomorphism of B with the induced topos $\mathcal{X}_{/U}$, [d1] (identified with U, or with B) allows one to recover operations of Γ on B, via the operations on U. Thus, the datum 171

[p. 86] of an operation of Γ on a topos B[i1] amounts to that of the datum of B as a Galois covering with group Γ of another topos (essential[ly] unique, then denoted (B, Γ) ...). Thus, to have [d1] Γ operate on $B_{D^*} \longrightarrow B_U$ is the same thing as inserting this [d2] arrow[i2] into a diagram like

$$\begin{array}{ccc} B_{D^*} & \longrightarrow & B_U \\ \downarrow & & \downarrow \\ B_{D^*,\Gamma} & \longrightarrow & B_{U,\Gamma} \end{array}$$

where the vertical arrows are Γ-Galois and the square is 2-Cartesian, or again (independently of the prior datum of B_{D^*}, B_U) it is giving oneself an essential[ly] commutative triangle of morphisms of topoi

$$\begin{array}{ccc} B_{D^*,\Gamma} & \longrightarrow & B_{U,\Gamma} \\ & \searrow \quad \swarrow & \\ & B_\Gamma & \end{array}$$

[scan 174]

If Γ operates on a multi-Galois topos, we see that (B, Γ) is also multi-Galois, and the situation of a multi-Galois topos B_U and of an operation of Γ on it amounts to that of a multi-Galois topos $B_{U,\Gamma}$[i1] and of a morphism $B_{U,\Gamma} \longrightarrow | \longleftrightarrow B_\Gamma$.

So the datum of a situation $B_{D^*} \longrightarrow B_U$ of multi-Galois topoi, and of an operation of Γ on it, amounts exactly to that of homomorphisms of multi-Galois topoi

$$B_{D^*,\Gamma} \longrightarrow B_{U,\Gamma} \longrightarrow B_\Gamma$$

†[d1]|The connectedness $B_{U,\Gamma}$ is 0-connected iff $\operatorname{card} \pi_0(B_U)/\Gamma = 1$, i.e. B_U nonempty and Γ transitive on $\pi_0(B_U)$. — Let us note that the situation 173

[scan 175]

[p. 87] envisaged at the beginning, with (X, S) over a field K, whence [d1] $B_{D^*} \longrightarrow B_U \longrightarrow B_\Gamma$ "$e_{\text{ét}}$[i1] ($\Gamma = \operatorname{Gal}(\overline{K}/K)$) can be interpreted as deduced from the "geometric" situation $(\overline{X}, \overline{S})$ over $\overline{K}$, or $B_{\overline{D}^*} \longrightarrow B_{\overline{U}}$, taking into account the operations of Γ on it. It turns out that for many questions, it is this "geometric" interpretation (in the strict sense, i.e. over $\overline{K}$ algebraically closed) with operations of a Galois group Γ, that is the most convenient.

If we look at an operation of Γ on a topos (B_{D^*} say), it operates on the discrete topos $B_{I|\pi_0}$ ($I = \pi_0(B_{D^*})$), and $B_{D^*} \longrightarrow B_I$ is compatible with the actions of Γ. [d2] But the [d3] topos[i2] $B_{(I,\Gamma)}$ is also that of Γ-sets over I (on which Γ operates) — an induced topos of B_Γ — [d4] its components[i3] that are connected correspond 174

[p. 89] seems therefore ripe at last to explain oneself about|with the hypothetical inverse operation of "drilling of|of the holes".

17. Supplement on the operations of finite groups on surfaces. (Supplement to § 7|§ 15)

Let U be a paracompact connected surface ! such that $\pi_1(U) \neq (1)$ i.e. $U \not\simeq S^2, \mathbb{R}^2$. We say that U is "anabelian" if π nonabelian (in which case Centre$(\pi) = 1$), i.e.|and if $U \not\simeq \mathbb{C}^*, S^1 \times S^1$. Let Γ be a finite group operating on U. Equivalent conditions :

b)|a) [d1] $\forall g \in \Gamma$, g_U is isotopic to the identity.

b') $\forall g \in \Gamma$, g_U is homotopic to the identity.

c) The outer operation of Γ on $\pi_1(U)$ is trivial.

d) (anabelian case)[i1] The extension $\mathcal{E}$ of Γ by π is isomorphic to a product extension, or (abelian case) [d2] it is central. [d3]

a)|d) (anabelian case) Γ operates trivially, (abelian|anabelian case) $\exists$ [d4] structure of a topological group[i2] [d5] on U (thus $U \simeq \mathbb{C}^*$or$S^1 \times S^1$), [illeg. 3] [d6] and a homomorphism of groups $\Gamma \longrightarrow U$, operating by translations

m295

Marginal note. [m295] That must be the only counterexample (in the case [d7] reversal of an orientation ...) In any case a counterexample must be such that (if Γ faithful, $\Gamma \simeq (\pm 1)$), operates by anti involution...

m296

Marginal note. [m296] It is prudent to assume that Γ operates preserving an orientation of U (assumed orientable), otherwise we have trouble, for example with $z \longrightarrow \overline{z}^{-1}$ from $\mathbb{C}^*$ into $\mathbb{C}^*$. It would be necessary to clarify|clear up the general situation (abelian case) in the theorem [illeg. 4] case of an anti-involution).

[scan 180]

Proof $a) \Longrightarrow b) \Longrightarrow b') \Longrightarrow c)$ trivial.

$c) \Longrightarrow d)$ In anabelian case, this comes from the fact that Centre$(\pi) = 1$ (and an extension of Γ by π is already defined by the outer action, [d1] as the inverse image of the example $1 \longrightarrow \pi \longrightarrow \mathrm{Aut}(\pi) \longrightarrow \mathrm{Autext}\,\pi \longrightarrow 1$]. In the abelian case, this is trivial.

$d) \Longrightarrow a)$ Is the not very|not obvious part. [d2] [d3] We may assume|Let us assume that Γ operates faithfully, [d4] Anabelian case[i1] [d5] If we had|with $\Gamma \neq 1$, let us fix[i2] a splitting of the extension $\mathcal{E}$ of Γ by π, we must have by the theorem of numbe[r] 15 $\pi^{\Gamma} = | \simeq 1$, now

the canonical splitting of $\pi \times | \rtimes \Gamma$ over Γ gives $\pi^{\Gamma} = \pi$, absurd.

Abelian case $U \simeq \mathbb{C}^*$ (more intrinsically, U a torsor under $U_0 = \pi \otimes_{\mathbb{Z}} \mathbb{C}/\pi$) or $U \simeq S^1 \times S^1$ (more intrinsically, U a torsor under $U_0 = \pi \otimes_{\mathbb{Z}} \mathbb{C}/\pi$).

I say that an action of Γ on U is here (up to [d6] homeomorphism|conjugation) defined by an action of $\Gamma|\pi$ on the torsor — the class

of isomorphism of such a torsor is moreover identified, by the cohomology exact sequence associated with the exact sequence

$$0 \longrightarrow \pi \longrightarrow \pi \otimes_{\mathbb{Z}} \mathbb{C}|\mathbb{R} \longrightarrow U_0 \longrightarrow 0$$

or $\pi \otimes_{\mathbb{Z}} \mathbb{R}$[i1] with a class of extensions of Γ by π. But to say that the action of Γ on π is trivial, means that the action of Γ on the torsor U under U_0 is by translations.

Corollary-scholium[i2] N.B. The "abelian" case is not quite proved, for want of having established the [d1] classification topological[i3] of the operations of a finite group on $\mathbb{C}^*$ or on $S^1 \times S^1$. However if in the abelian case we assume in advance that $U^\Gamma \neq \emptyset$, then [d2] it is still true that the trivial operation of Γ on π is equivalent to the triviality of the action of Γ on U. For we are reduced to the case where Γ operates faithfully, and to proving in this case that if the operation of Γ on the π is trivial, we have $\Gamma = 1$. And we do as above in the anabelian case.

the datum of an $L_i \subset \pi$ in the class i is equivalent to the datum of a pair $(\widetilde{D}_i, \lambda|\,\mathrm{id})$ of a $\widetilde{D}_i \in \mathrm{Ob}\,\Pi_1 B_{D_i}$ and an isomorphism from $\rho_!(\widetilde{D}_i) =: |\, = \widetilde{U}$ onto $\widetilde{U}_0$.

When [d1] the topos-theoretic situation is realized from a topological situation (X, S), and we define $\widetilde{U}_0$ by means of a base point $a \in U$, then the standard way of defining an $L_i \subset \pi = \mathrm{Aut}(\widetilde{U}_0) = \pi_1(U, a)$ is to choose a small disk Δ_i around s_i in X,

and a point b_i[i1] on the boundary, and a homotopy class of paths (in $U|X - (\mathring{\Delta}_i - \{s_i\}) = V_i$)[i2] from a to b_i, and to take the group L_i generated by either one of the two corresponding loops around s_i (which give [d3] opposite elements of π). We see that we thus find a surjective map from

$$\mathrm{Isom}_{\Pi_1 V_i}(a, b_i) \simeq \mathrm{Isom}_{\Pi_1 U}(a, b_i)$$

[d4] onto the set of $L_i \subset \pi$ in the class $i|\Pi$, a map [d5] compatible with the

[p. 92]

natural action of π (operating on $\mathrm{Isom}_{\Pi_1 U}(a, b_i)$ in the obvious way by composition, and on the set of L_i by inner automorphisms. [d1] Here, the [d2] link with the "abstract" topos-theoretic description is established as follows: the choice of b_i can serve as a base|fixed point for defining a universal covering of $\Delta_i \smallsetminus \{s_i\} \overset{\sim}{\hookleftarrow} D_i^*$, whence an object $\rho_!(\widetilde{D}_i^*(b_i))$, and [d3] the $L_i \subset \pi$ correspond (according to the abstract description)[i1] to the isomorphisms from $\widetilde{U}_0 = \widetilde{U}(a_i)$ onto $D_i^*(b_i)|\widetilde{D}_i^*(b_i)$ modulo composition with an automorphism of $D_i^*(b_i)|\widetilde{D}_i^*(b_i)$ coming from an automorphism of $D_i^*(b_i)|\widetilde{D}_i^*(b_i)$ – but the isomorphisms [d4] $\widetilde{U}(a_i) \overset{\sim}{\to} \rho_!(\widetilde{D}_i^*(b_i))$ correspond precisely to the classes of paths from a to b_i.

Let us consider an object of $\Pi_1 B_{D_i^{*\prime}}$, i.e. a pair (π', L_i'). Let π be the quotient group of π' by the invariant subgroup of π' [d5] generated[i2] by L_i'. I say that up to unique isomorphism (actual isomorphism of groups, not merely outer!) it does not

depend on the choice of the object $\widetilde{D}_i^*$ of $\Pi_1 B_{D_i'^*}$. Indeed, $\pi = \pi(\widetilde{D}_i^*)$ depends functorially on $\widetilde{D}_i^*$, and everything comes down to seeing that this functor is constant, i.e. that the operation of

$$\mathrm{Aut}(\widetilde{D}_i^*) \simeq T \simeq L_i \quad \text{on} \quad \pi = \pi(\widetilde{D}_i^*)$$

is trivial. Now let $u \in L_i$, the|its automorphism of π which it defines is defined by the inner automorphism $\mathrm{int}(u)$ by passage to the quotient, hence (since u becomes 1 in π) it is trivial. Easy.

We thus find a functor

$$\begin{array}{c}\text{Outer groups with loops } \pi' \\ \text{of type } g, \nu+1 \text{ equipped with a} \\ \text{loop class } i \in I(\pi')\end{array} \longrightarrow \begin{array}{c}\text{groups} \\ \text{(realized)} \\ \text{with loops, of} \\ \text{type } g, \nu\end{array}$$

$$(\pi', i) \longmapsto \beta(\pi', i) \qquad [\text{“plugging the hole } i\text{”}]$$

which is expressed by a group homomorphism

$$\operatorname{Aut} \operatorname{ext}(\pi', i) \longrightarrow \operatorname{Aut} \pi \tag{*|5}$$

where $\pi = \beta(\pi', i)$

$$\left(\begin{array}{l} \overset{\text{definition}}{=} \text{ set of categorical automorphisms} \\ \text{of } \pi' \text{ respecting the loop} \\ \text{structure and fixing the loop} \\ \text{class } i \end{array} \right)$$

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 186]

[p. 93]

From the geometric point of view, this fact (existence of this functor), merely expresses the fact that after “plugging the hole” i, we have a [d1] $U = U' \cup \{s_i\}$ equipped with a point s_i which we can use as a base point canonical[i1] to calculate $\pi_1(U)$.

We can also say that the choice of i makes it possible to construct the partial amalgamated sum (plugging holes partially[i2]) B_{U^*}

and $B_{s_i} \longrightarrow B_{U^*}$ supplies a geometric point of B_{U^*} which makes it possible to describe a canonical object of $\Pi_1 B_{U^*}$ (universal covering relative to this point) whence canonically a group π, which of course is a group with loops of type $g, \nu - 1$.

Theorem Suppose g, ν are such that not

only the groups π'_s of type g, ν, but also the groups π (of type $g, \nu - 1$) are anabelian, i.e.

$$2g + \nu \geq \mid \leq 4 \quad [\text{thus } g \geq 2, \text{ or } g \geq \mid = 1, \nu \geq 2, \text{ or } g = 0, \nu \geq 4].$$

Then the preceding functor $(\pi', i) \longrightarrow \pi$ is an equivalence of categories, in other words (since these are 0-connected groupoids)

$$\operatorname{Aut}\operatorname{ext}(\pi', i) \longrightarrow \operatorname{Aut}(\pi)$$

is an isomorphism.

Let us note for this that we have the exact sequence

$$1 \longrightarrow \pi \longrightarrow \operatorname{Aut}(\pi) \longrightarrow \operatorname{Aut}\operatorname{ext}(\pi) \longrightarrow 1 :$$

(for $\operatorname{Centre}\pi = 1$ by the anabelian hypothesis on π), now we are going to define an exact sequence

$$1 \longrightarrow \pi \longrightarrow \operatorname{Aut}\operatorname{ext}(\pi', i) \longrightarrow \operatorname{Aut}\operatorname{ext}(\pi) \mid \operatorname{Aut}\operatorname{ext}(\pi') \longrightarrow 1$$

and a homomorphism of extensions from this one

into the preceding one (which will necessarily be an isomorphism).

We may assume $T = \mathbb{Z}$, we consider the standard|standard groups with loops $\Pi_{g,\nu+1}$, $\Pi_{g,\nu}$. Let us put

$$\operatorname{Aut}\operatorname{ext}_{\text{lac}}(\Pi_{g,\nu}) = \mathcal{T} \mid \mathfrak{T}^{00\mid\infty}_{g,\nu}$$

inducing the identity on $I(\Pi_{g,\nu})$ and on $T(\Pi_{g,\nu})$[i1] (Teichmüller group of index g, ν), we know that (for $2g + \nu \geq 3$) $\mathcal{T}_{g,\nu}$ is the fundamental group of the complex modular topos $M_{g,\nu}$[i2] of complex curves ([d1] projective nonsingular) connected, of genus g, with a system of ν given distinct points $s_1 - s_\nu$. [m303]

Marginal note. [m303] N.B. the universal covering of $M_{g,\nu}$ is contractible, Teichmüller.

Now the modular topos $M_{g,\nu+1}$ is none other than [d2] the "universal complex curve [d3] of genus g with ν numbered holes" over $M_{g,\nu}$ [for giving ourselves a curve U'[i3] of genus g with $\nu + 1$ holes $x_1 - x_{\nu+1}$[i4] amounts to the same as giving ourselves one U[i5] with ν numbered holes $x_1 - x_\nu$, plus a [d4] point of U [d5]), whence a homotopy exact sequence

$$\begin{array}{ccccccccc}
\pi_2 \mid \Pi_2(M_{g,\nu}, \xi) & \longrightarrow & \pi_1(U) & \longrightarrow & \pi_1(M_{g,\nu+1}) & \longrightarrow & \pi_1(M_{g,\nu}) & \longrightarrow & \pi_0(U) \\
 & & \| & & \| & & \wr & & \| \\
0 & \longrightarrow & \pi = \Pi_{g,\nu} & \longrightarrow & \mathcal{T}^{00}_{g,\nu+1} & \longrightarrow & \mathcal{T}^{00}_{g,\nu} & \longrightarrow & 1
\end{array}$$

[p. 95]

in such a way that $(B_{D^*}, B_U, \widetilde{U})$ is deduced from it by the operation of "plugging the hole D_i^*".

These constructions are so functorial, that they commute with actions of groups Γ. If a group Γ operates on a group with loops π of type g, ν, (not merely by outer automorphisms), then we deduce from it an outer operation of Γ on a π' with loops of type $g, \nu + 1$, which fixes a privileged loop class $i \in I$.

But then, in the corresponding extension

$$1 \longrightarrow \pi' \longrightarrow E' \longrightarrow \Gamma \longrightarrow 1,$$

Let us choose an $L'_i \subset \pi'$ and let $\mathcal{E}'_i|E'_i$ be the normalizer of L_i in $\mathcal{E}'|E'$ – we find

$$1 \longrightarrow \underset{\simeq T}{L'_i} \longrightarrow \mathcal{E}'_i|E'_i \longrightarrow \Gamma \longrightarrow 1$$

Scans 191–200

[scan 191]

(this works without a finiteness hypothesis on Γ, the universal case being the one where Γ is the Teichmüller group of π' fixing i i.e. $\mathrm{Autext}_{\mathrm{lac}}(\pi'; i) \simeq \mathrm{Aut}_{\mathrm{lac}}(\pi)$). I say that if Γ operates faithfully on π i.e. if its outer operation on π' is faithful, and if Γ is finite, Then Γ is necessarily cyclic (case $\Gamma = \Gamma^0$)[i1] or dihedral ($\Gamma \neq \Gamma^0$), and that if in addition $\Gamma = \Gamma^0$, then [d1] $\mathcal{E}_i \simeq \mathbb{Z}|\mathcal{E}'_i \simeq \mathbb{Z}$ i.e.[i2] $\exists!$ isomorphism $T \xrightarrow{\sim} \mathcal{E}_i|T \xrightarrow{\sim} \mathcal{E}'_i$ such that $T \xrightarrow{k'_i} \mathcal{E}'_i$ identifies with $n\,\mathrm{id}_T$ (so that we find $\Gamma \simeq \mathcal{E}'_i/n\mathcal{E}'_i \simeq T \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z}$, if $n = \mathrm{card}\,\Gamma$ ...

Changing notation, this amounts to the Theore[m] Let Γ be a finite group operating faithfully on an outer|outer[ly] group with loops π of type [d2] $(g, \nu + 1)$ $(\nu \geq 0)$[i3], leaving an $i \in I(\pi)$ fixed, Then Γ is cyclic (if $\Gamma = \Gamma^0$) or dihedral (if $\Gamma \neq \Gamma^0$), and in the extension [m305]

Marginal note. [m305] to the same there is equivalence, if in the theorem, we assume the type (g, ν) anabelian — otherwise the theorem is a little more general

this homomorphism is an isomorphism (from which would follow|will follow the other assertions), or what amounts to the same since Γ^0 and T_n are both of order n, that it is a monomorphism. Replacing Γ^0 by the kernel of $\Gamma^0 \to \mathbb{Z}/n\mathbb{Z}$, we may assume that the homomorphism in question[i1] is zero, and we must prove that this implies that the action of Γ^0 is trivial (which, since by hypothesis the action of Γ is faithful, implies $\Gamma^0 = \{1\}$, OK.) So theorem is reduced to the

fundamental lemma. Every direct[i2] outer automorphism u of finite order n[i3] of a group with loops π, which fixes a loop class i and is such that the extension of $\mathbb{Z}/n\mathbb{Z}$ by $L_i \in i$ defined by u is trivial, is trivial.

The hypothesis means that u lifts to an automorphism u_0 of π, which normalizes L_i, and which is also of order n, (or of finite order, this amounts to the same|⇒ taking into account that [d1] T has no elements of finite order) [p. 192]

[p. 97] then u_0 is trivial, i.e. this is equivalent to the Corollary. Every direct[i1] automorphism of finite order u_0[i2] of a group with loops π, which is direct and[i3] which normalizes a loop subgroup L_i (i.e. which centralizes L_i), is reduced to the identity. [m307]

In the lemma or its corollary

Marginal note. [m307] N.B. (the case $g = 0$, $\nu + 1 = 1$ or $\nu + 1 = 2$ is trivial, the case $\nu + 1 = 3$ ($(g, \nu) = (0, 2)$ abelian!) is not trivial on the other hand, nor the case $g = 1$, $\nu + 1 = 1$ i.e. $(g, \nu) = (1, 0)$ abelian. Yet the result should be valid also in this|these cases.)

To prove it, we are reduced at once[i4] to the case where u_0 is [d1] such that $u_0^p = \mathrm{id}$, where[i5] p is a prime number — i.e. u_0 corres- ponds to an operation in the strict sense (not on[ly] outer) of $\mathbb{Z}/p\mathbb{Z}$ [d2] by automorphisms of π. But (whether or not we can find such a p) let us consider the case where we know that the outer operation of $\Gamma = \mathbb{Z}/n\mathbb{Z}$ [n = order of u] on π is realized geometrical[ly], by a (faithful) operation of $\Gamma = \mathbb{Z}/n\mathbb{Z}$ on a U of type $(g, \nu + 1)$. [d3] [m308]

Marginal note. m308 $U = X \setminus S$, $S \simeq I$, X compact of genus g the puncture|the part s_i of S corresponding to a fixed point of Γ operating on U.

Manuscript:* We know that the (liftings) of the outer automorphisms to automorphisms a genuine operation, correspond to the fixed points [illeg. 1] of Γ in U; and the extension of let a be the fixed point of Γ corresponding to the given operation, so that we have a canonical isomorphism compatible with Γ $\pi = \pi_1(U, a)$.
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 195]

We express the hypothesis of the "genuine"i1 operation of Γ on π, d1 centralizing an L_i, by saying that the outer operation gives a trivial extension of Γ by $L_i \simeq T$. But we know moreover in the geometric case and faithful operationi2 that it is not trivial !

It would therefore suffice, d2 to prove the fundamental lemma, to know that every outer action [faithful]i3 of a cyclic group on a group with loops of type $(g, \nu + 1)$ is realizable, and it even suffices to know this for a cyclic group of prime order. isi4 Now unless I am mistaken this result is well known (even for solv- able groups ...). — so that the funda- mental lemma seems proved. I have only a doubt whether it is proved in the general case of a (g, ν), d3i5 or only for $g \geq 2$,i6 $\nu = 0$. But d4 d5 m309

[p. 98] d1 if this is indeed so, I think that (for $g \geq 2$ at the very least) we get by with dévissage for the case of arbitrary ν — and the case $g = 0, 1$ would require also[i1] a separate treatment. I will come back to this later, and prefer for the moment to admit the "fundamental lemma", and examine consequences and corollaries of it.

For an outer faithful[i2] action of a finite Γ on an anabelian group with loops π, we d2 corresponding to an extension $\mathcal{E}$ of Γ by π, we have therefore established a) that the partial splittings of it can only be made over d3 subgroups Γ' of Γ such that Γ'^0 is cyclic, and Γ' dihedral if $\Gamma' \neq \Gamma'^0$, and that b) for every class of [illeg. 2] of such partial splittings over $\Gamma' \subset \Gamma^0$, we have a corresponding canonical isomorphism $\Gamma' \simeq T_n$ $(= T/nT)$, where $n = \operatorname{card} \Gamma'$. m310

previously obtained for the case of a realizable operation. [There was moreover no reason to restrict ourselves to the anabelian case, as long as we assume $\pi \neq 0$ (essentially empty case!)[i1], which includes the abelian[i2] cases $g = 0$, $\nu = 2$ and $g = 1$, $\nu = 0$, for which a direct treatment is possible, and has already been given essentially, those cases [d1] where|if one[i3] starts with an extension (not with an "outer" action i.e. here an action plain and simple of Γ on $\pi \simeq \mathbb{Z}$ or $\mathbb{Z}^2$), being always realizable. (N.B. [d2] In this[i4] case, the hypothesis of a faithful action is replaced by the one that the extension is [d3] a product extension[i5] over|under no subgroup $\Gamma' \subset \Gamma^0$ with $\Gamma' \neq 1$ ....).

There remain however other results of the realizable case, which would have to be examined in the general case :

c) If Γ is a [d4] finite subgroup of $\mathrm{Aut}_{\mathrm{lac}}(\pi)$ i.e. a finite group operating faithfully on π, do we have $\pi^{\Gamma} = \{1\}$? [m311]

Marginal note. [m311] We may assume $\Gamma = \Gamma^0$ hence Γ generated by a direct automorphism u or Γ generated by an anti-automorphism of order 2

Scans 201–210

[scan 201]

Proof. d1

Let us prove d). d4 We identify Γ', Γ'' with subgroups of Γ, and put $\Gamma_0 = \Gamma' \cap \Gamma''$. Let $\mathcal{E}^!$ be the subgroup of $\mathcal{E}$ consisting of the $g \in \mathcal{E}$ such that $\mathrm{int}(g).\Gamma_0$ is π-conjugate to Γ_0 and whose image in Γ d5 centralizes Γ_0. d6 We have $\mathcal{E}^! \supset \pi$, and $\mathcal{E}^!$ is therefore the inverse image of a subgroup $\Gamma^!$ of Γ, which centralizes Γ_0 d7, and which contains Γ' and Γ'' (for $\mathcal{E}^!$ contains the centralizer of Γ_0 in $\mathcal{E}$, hence Γ' and Γ''). Replacing Γ by $\Gamma^!$, $\mathcal{E}$ by $\mathcal{E}^!$ if necessary, we may suppose $\mathcal{E} = \mathcal{E}^!$, $\Gamma = \Gamma^!$ i.e. that $\Gamma_0 \subset$ Centre of Γ, and that $\Gamma_0 \hookrightarrow \mathcal{E}$ invariant modulo π-conjugation under Γ.

[scan 204]

[p. 102] 19. Teichmüller tower.

Let $g \in \mathbb{N}$, and[i1] X_g be a compact orientable surface of genus g, [d1] [|] $(a_{g,i})_{i \in \mathbb{N}^*} = (a_{g,1}, a_{g,2}, \ldots)$]|[a sequence of distinct points of X_g. We put for $\forall \nu \in \mathbb{N}$

$$(1) \qquad S_{g,\nu} = \{x_{g,i} | a_{g,i} \mid 0 \leq i \leq \nu - 1\} \qquad \text{thus } \nu = \mathrm{card}\, S_{g,\nu}$$

$$(2) \qquad U_{g,\nu} = X_g - S_{g,\nu}.$$

We thus have $S_{g,0} = \emptyset$, $U_{g,0} = X_g$; The $S_{g,\nu}$ form a strictly[i2] increasing sequence of finite subsets of X_g, the $U_{g,\nu}$ a strictly decreasing sequence of open subsets of X_g. In what follows we shall take $U_{g,\nu}$ as the standard surface (oriented, or orientable), of type (g, ν).

N.B. we have $a_{g,\nu} \in U_{g,\nu}$

Let

$$A_g = \mathrm{Aut}(X_g) \tag{3}$$

be the group of automorphisms of X_g, equipped with the topology of uniform convergence of u and of its inverse. We put

$$A_{g,\nu} = \{u \in A_g \mid u(S_{g,\nu}) = S_{g,\nu}\} \subset A_g \tag{4}$$

thus $A_{g,\nu}$ is a subgroup of A_g. We have a canonical isomorphism $u \mapsto u|U_{g,\nu}$

$$A_{g,\nu} \xrightarrow{\sim} \mathrm{Aut}(U_{g,\nu}). \tag{5}$$

m318

Marginal note. [m318] N.B. This is probably|probably[i3] an isomorphism topologically, when $A_{g,\nu}$ is equipped with the topology induced by A_g, and $\mathrm{Aut}(U_{g,\nu})$ with the usual topology of compact [illeg. 1] convergence of u and its inverse.

[d2] We have [d3] canonical surjective homomorphism

$$A_{g,\nu} \longrightarrow \mathrm{Aut}(S_{g,\nu})(\overset{(\text{canonical})}{\simeq} \mathfrak{S}_\nu), \tag{6}$$

[scan 208]

[p. 104]

$$(23) \qquad S = \{x \in X_g \mid ux = x \quad \forall u \in A^!_{g,S}\} = X_g^{(A^!_{g,S})}$$

$$(24) \qquad \begin{aligned} S &= \{x \in X_g \mid A_{g,S}.x \text{ finite}\} \\ &= \{x \in X_g \mid A_{g,S}.x \neq X_g\} \end{aligned} \qquad \forall S \in \mathcal{P}_\nu(X_g)$$

We also have some|†[d1] canonical maps of homogeneous spaces under A_g

$$(25) \qquad S \longmapsto A^\circ_{g,S}$$

$$\mathcal{P}_\nu(X_g) \longrightarrow \begin{array}{l} \text{set of conjugates} \\ \text{of the } A^\circ_{g,\nu} \text{ in } A_g \\ \simeq A_g/\operatorname{Norm}(A^\circ_{g,\nu}) \end{array}$$

which is not only surjective, but also injective, for we have the following relation, which strengthens (23) and[i1] (24), $\forall S \in \mathcal{P}_\nu(X_g)$

$$(26) \qquad \begin{aligned} S &= \{x \in X_g \mid A^\circ_{g,S}.x = \{x\}\} = X_g^{A^\circ_{g,S}} \\ &= \{x \in X_g \mid A^\circ_{g,S}.x \text{ finite}\} \\ &= \{x \in X_g \mid A^\circ_{g,S}.x \neq X_g\}. \end{aligned}$$

[d2] Thus we have for $\forall \nu$

$$(27) \qquad A_{g,\nu} = \operatorname{Norm}_{A_g}(A_{g,\nu}|A_{g,x}) = \operatorname{Norm}_{A_g}(A^!_{g,\nu}) = \operatorname{Norm}_{A_g}(A^\circ_{g,\nu}).$$

Let G be a topological group, equipped with a conjugacy class $\mathcal{E}|\mathcal{X}$ of subgroups, [d3] G_1 in this class. We say that

$G, \mathcal{X}$ is a Teichmüller [d1] pair[i1] of type g, if there exists an isomorphism of topological groups $G \simeq A_g$, taking $\mathcal{E}|\mathcal{X}$ to the conjugacy class of A_1. It amounts to the same thing to say that[i2] [d2] [d3] $\mathcal{X}$, [d4] equipped with the topology of a[i3] homogeneous space under G, is [d5] a compact orientable surface of genus g, [d6] say $\mathcal{X}|\mathfrak{X}$, and that [d7] the map[i4] natural

$$G \longrightarrow \mathrm{Aut}(\mathcal{X}) \tag{28}$$

is a homeomorphism of topological groups. We then see that by $(G, \mathcal{X}) \longrightarrow \mathcal{X}$ from[i5] the category of Teichmüller pairs of type g, to that of compact oriented surfaces, is an equivalence of categories. It follows that [d8] for an automorphism u[i6] of the topological group G, u is inner iff it

[p. 105] preserves the class $\mathcal{X}$ i.e. iff $u(G_1)$ is conjugate to G_1. Moreover the center of G is trivial, i.e.

We can give an analogous description for the category of oriented surfaces of genus g with ν holes (i.e. homeomorphic to $U_{g,\nu}$) in terms of a topo- logical group $G_\nu (\simeq A_{g,\nu})$ and of a conjugacy class $U_\nu | \widetilde{U}_\nu$ of[i1] subgroups H_ν of it ($\simeq A_{g,\nu} \cap A_{g,\nu+1}$), with the conditions that $(G_\nu, \{H_\nu\})$ be isomorphic to $(A_{g,\nu}, A_{g,\nu} \cap A_{g,\nu+1})|\}$, or else that U_ν (space [illeg. 1] topology of a homogeneous space)[i2] be an oriented surface of type (g, ν), and that the [d1]canonical homomorphism

$$G \longrightarrow \mathrm{Aut}(U_\nu) \tag{29}$$

be a homeomorphism of topological groups. We then find an equivalence between the category of Teichmüller pairs $(G_\nu, \{H_\nu\})$ of type (g, ν), and that of orientable surfaces of type (g, ν). We find again

[scan 211]

that the automorphisms of such a G_ν ($\simeq A_{g,\nu}$) which fix the class U_ν i.e. which transform|transport H_ν into a conjugate, are inner, and that the center of H_ν is $\{1\}$.

In fact, U_ν can also be interpreted as a homogeneous space under G_ν°, and not only under G_ν, more generally we have that G_ν° is transitive on U_ν, and even on $\mathcal{P}_{\nu'}(U_\nu)$ for every $\nu' \in \mathbb{N}^*$.

Returning to the model situation with $U_{g,\nu}$, we find

$$\begin{aligned} U_{g,\nu} &\simeq A_{g,\nu}^{\dagger|\bullet}/\underbrace{A_{g,(\nu,\nu+1)}}_{\substack{\| \text{ definition} \\ A_{g,\nu}\cap A_{g,\nu+1}}} \\ &\simeq A_{g,\nu}^{\circ}/\underbrace{B_{g,(\nu,\nu+1)}}_{\substack{\| \text{ (definition)} \\ A_{g,\{\nu+1\}}\cap A_{g,\nu}^{\circ}=\{u\in A_{g,\nu}^{\circ}\mid u.a_{g,\nu}=a_{g,\nu}\}}} . \end{aligned} \tag{30}$$

We thus have [d3] [d4] by inverse[i1] diagram of inclusions of subgroups of $A_{g,\nu}$: [d5] 210

[p. 106]

(31)

m324

Marginal note. m324 N.B. $A_{g,(\nu,\nu+1)}$, stabilizer [illeg. 2] in $(A_{g,\nu} = \mathrm{Aut}(U_{g,\nu}))$ of the marked point $a_{g,\nu}$ of [illeg. 1], deserves a simpler notation, for example $A^\bullet_{g,\nu}$ (the exponent $\bullet$ here to emphasize [illeg. 3] pointed|pointed in $U_{g,\nu}$).

The two squares are cartesian, and the horizontal inclusions (except the one in brackets in the 2nd row)i1 are inclusions of invariant subgroups invariant eveni2 (in the largest group, $A_{g,\nu}$ resp. $A_{g,(\nu,\nu+1)}$).

[The equality $B^\circ_{g,\nu} = A^{!\circ}_{g,\nu+1}$ d1 (which refines the trivial inclusion $B^\circ_{g,\nu} \subset A^{!\circ}_{g,\nu+1}$ by the reverse inclusion $A^{!\circ}_{g,\nu+1} \subset B^\circ_{g,\nu}$, equivalent to $A^{!\circ}_{g,\nu+1} \subset B_{g,\nu}$) comes from the inclusion

$$A^{!\circ}_{g,\nu+1} = A^\circ_{g,\nu+1} \subset A^{!\circ}_{g,\nu} = A^\circ_{g,\nu} \quad (\text{whence : } A^\circ_{g,\nu+1} \subset A_{g,\nu+1} \cap A^\circ_{g,\nu} = B_{g,\nu}).$$

]

The three vertical inclusions define three homogeneous spaces, and d2 inclusion homomorphisms between them which are bijective

$$(U_{g,\nu} \simeq) \quad A_{g,\nu}/A_{g,(\nu,\nu+1)} \xleftarrow{\sim} A^!_{g,\nu}/A^!_{g,\nu+1} \xleftarrow{\sim} A^\circ_{g,\nu}/B_{g,\nu},$$

with (transitivity !)i4 and d3 d4 the quotient groups denoted $\mathfrak{S}_\nu$ and $\Gamma^!_{g,\nu}$i5 defined by the horizontal inclusions of the first row, are isomorphic via the vertical inclusions to the corresponding quotients in the second row. Thus the extension of groups

$$(12) \qquad 1 \longrightarrow \Gamma^!_{g,\nu} \longrightarrow \Gamma_{g,\nu} \longrightarrow \mathfrak{S}_\nu \longrightarrow 1$$

can d5 be deduced equally well from 211

the first row of (31), or from the first three terms of the second, in particular

$$\begin{cases} \mathfrak{S}_\nu \simeq A_{g,(\nu,\nu+1)}/A^!_{g,\nu+1} \\ \Gamma^{\bullet|}_{g,\nu} \simeq A_{g,(\nu,\nu+1)}/B_{g,\nu} \\ \Gamma^!_{g,\nu} \simeq A^!_{g,\nu+1}/B_{g,\nu}. \end{cases} \tag{32}$$

Thus the canonical[i1] torsor with group $A_{g,(\nu,\nu+1)} = (A_{g,\nu})_{a_{g,\nu}}$[i2] over the homogeneous space[i3] $U_{g,\nu}$, and the one[i4] of the group $A^!_{g,\nu+1}$ ($\subset A_{g,(\nu,\nu+1)}$) which gives rise to it, is in either case deduced, by extension of the structure groups, from a torsor with group $B_{g,\nu}$ (whose fiber at $x \in U_{g,\nu}$ is the space of[d1] $u \in A^\circ_{g,\nu}$ such that $u(a_{g,\nu}) = x$). $= (A^\circ_{g,\nu})_{a_{g,\nu}}$[i5]

The associated Galois[i6] covering, with group $B_{g,\nu}/B^\circ_{g,\nu}$, is therefore also the homogeneous space $A^\circ_{g,\nu}/A^\circ_{g,\nu+1}$, which is obviously connected, and pointed over $a_{g,\nu} \in U_{g,\nu}$. Put[d2 d3] 212

$$\widetilde{U}_{g,\nu} = A^\circ_{g,\nu}/A^\circ_{g,\nu+1}. \tag{33}$$

Theorem. $\widetilde{U}_{g,\nu}$ is simply connected (if $(g,\nu) \neq (1,0)$ and $(g,\nu) \neq (0,2)$)[i7] (and even contractible if $(g,\nu) \neq (0,0)$) and thus identifies with the universal covering pointed at $a_{g,\nu+1}$ of $U_{g,\nu}$.

m327

Marginal note. [m327] This relation|This assertion plausible [illeg. 3] in the anabelian cases $2g+\nu \geq 3$, we shall see [illeg. 3] in abelian case [illeg. 4] reasonable [illeg. 3]. We must exclude the cases $(1,0)$ and $(0,2)$.

Corollary. We have a canonical isomorphism

$$B_{g,\nu}/B^\circ_{g,\nu} \simeq \pi_1(U_{g,\nu}; a_{g,\nu}) \overset{\text{definition}}{=} \Pi_{g,\nu}. \tag{34}$$

[p. 107] Proof of the Theorem, in terms of "well-known" things. The d1 homotopy exact sequence for the fibration of $A^\circ_{g,\nu}$ over

$$A^\circ_{g,\nu+1}/A^\circ_{g,\nu} \simeq \widetilde{U}_{g,\nu}$$

d2

$$\longrightarrow \pi_{i+1}(\widetilde{U}_{g,\nu}) \longrightarrow \pi_i(A^\circ_{g,\nu+1}) \longrightarrow \pi_i(A^\circ_{g,\nu}) \longrightarrow \pi_i(\widetilde{U}_{g,\nu}) \longrightarrow \pi_{i-1}(A^\circ_{g,\nu+1}) \tag{35}$$

and it shows that $\pi_1(\widetilde{U}_{g,\nu})$ is isomorphic to the cokernel of

$$\pi_1(A^\circ_{g,\nu}) \longrightarrow \pi_1(A^\circ_{g,\nu+1}),$$

whose kernel is a quotient of $\pi_2(\widetilde{U}_{g,\nu})$...

If $(g,\nu) \neq 0$, we know that $\pi_i(\widetilde{U}_{g,\nu}) = 0$ for $i \geq 2$ (for every covering of $U_{g,\nu}$) hence d4

$$\left\{ \pi_i(A^\circ_{g,\nu+1}) \longrightarrow \pi_i(A^\circ_{g,\nu}) \text{ is } \begin{cases} \text{if } (g,\nu) \neq (0,0) \\ \begin{cases} \text{bijective if } i \geq 2 \\ \text{injective with invariant image if } i = 1 \end{cases} \\ [\text{the cokernel is } \simeq \pi_1(\widetilde{U}_{g,\nu})] \end{cases} \right. \tag{36}$$

and we want to prove that it is even bijective for $i = 1$. The thing to remember easy is this :

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 215]
d1

Well-known theorem. Equivalent conditions on the pair $(g,\nu)\in\mathbb{N}\times\mathbb{N}$:

a) $2g+\nu\geq 3$ i.e. we are not in one of the four exceptional cases $(1,0)$, $(0,0)$, $(0,1)$, $(0,2)$.
b) $\pi_1(U_{g,\nu})$ nonabelian
c) $A^\circ_{g,\nu}$ is simply connected ($(g,\nu)\neq(0,1)$)
d) $A_{g,\nu}$ is contractible and $(g,\nu)\neq(0,1)$.

d5 abelian case

In any case, whether or not these conditions are satisfied, we have d6

$$\pi_i(A^\circ_{g,\nu})=0 \qquad i\geq 2, \quad (g,\nu)\neq 0$$

(i.e. the[i2] $A^\circ_{g,\nu}$ are classifying spaces of discrete groups $\pi|K$, with the sole exception of $A^\circ_{0,0}\simeq \mathrm{Aut}(S^2)^\circ$).

Taking (36) into account, this Theorem is equivalent to the relations

$$\begin{aligned}&\pi_i(A^\circ_{g,0})=0 \quad \text{if } g\geq 2,\ i\geq 1 \quad \text{i.e. for } g\geq 2,\ A_{g,0} \text{ is contractible}\\ &\pi_i(A^\circ_{1,1})=0 \quad \text{for } i\geq 1 \quad \text{i.e. } A^\circ_{1,1} \text{ is contractible}\\ &\pi_i(A^\circ_{0,3})=0 \quad \text{for } i\geq 1 \quad \text{i.e. } A^\circ_{0,3} \text{ is contractible.}\end{aligned} \tag{37}$$

$$\left.\begin{array}{ll}\pi_i(A^\circ_{1,0}) = 0 & \text{for } i \geq 2 \\ \pi_i(A^\circ_{0,1}) = 0 & \text{for } i \geq 2\end{array}\right\} \quad \text{i.e. } A^\circ_{1,0} \text{ and } A^\circ_{0,1} \text{ are } K(\pi, 1). \tag{38}$$

d7

and they have as a consequence that $\widetilde{U}_{g,\nu}$ is simply connected in the anabelian cases $2g+\nu \geq 3$. To know how things stand 214

[scan 217]

is a homotopy equivalence.

The fact that if U is a homogeneous space of a group that is topological, by a connected subgroup,[i1 d1], then $\pi_1(U)$ is abelian, comes from the homotopy exact sequence, and from the fact that the π_1 of a topological group is commutative. The converse in the case of topological surfaces [illeg. 1] remarkable! The corollary gives us

m333

Marginal note. m333 We have a more precise result: If k is the smallest integer such that $(g, \nu+k)$ is an anabelian pair, then $\dim G = k$, and G is simply transitive on the set of k-tuples $(x_1, \dots, x_k)$ of distinct points of $U_{g,\nu}$, whence it follows at once that every element of $A_{g,\nu}$ can be written in a unique way as a product gu, with $g \in G$, $u \in A_{g,(\nu,\nu+k)}$, so [d2] $A_{g,\nu}$ is homeomorphic to $A_{g,(\nu,\nu+k)} \times G$. As G is connected, we conclude from this

$$\Gamma_{g,\nu} \simeq \Gamma_{g,(\nu,\nu+k)} \subset \Gamma_{g,\nu+k},$$

and $A^\circ_{g,\nu} \simeq G \times A^\circ_{g,\nu+k}$, and as $A^\circ_{g,\nu+k}$ is contractible|∞-connected, we conclude from this [illeg. 2] $G \xrightarrow{\simeq} | \simeq A^\circ_{g,\nu}$.

$$\begin{aligned} &\pi_1(A^\circ_{1,0}) \simeq \mathbb{Z} \times \mathbb{Z} \quad \text{i.e. } A^\circ_{1,0} \simeq K(\mathbb{Z} \times \mathbb{Z}, 1) \\ &\pi_1(A^\circ_{0,2}) \simeq \mathbb{Z} \qquad \text{i.e. } A^\circ_{0,\nu|2} \simeq K(\mathbb{Z}, 1) \\ &\pi_1(A^\circ_{0,1}) \simeq \mathbb{Z} \qquad \text{i.e. } A^\circ_{0,1} \simeq K(\mathbb{Z}, 1). \end{aligned} \tag{39}$$

m336

$G \simeq \mathbb{U} \times \mathbb{U}|U$ (elliptic curve)

Marginal note. m336 $G \simeq \mathrm{Aff}(1, \mathbb{C})$ (homotopic to $\mathbb{C}^*$ by the inclusion)

$G \simeq \mathbb{C}^* = \mathrm{GL}(1, \mathbb{C})$

$A^\circ_{0,0} = \mathrm{Aut}(S^2) \simeq \mathrm{Aut}(\mathbb{P}^1_{\mathbb{C}})$ is homotopic by the inclusion to its subgroup $\mathrm{GP}(1, \mathbb{C})$ (hence to its maximal compact subgroup $\mathrm{SO}(3, \mathbb{R})/\{\pm 1\}$), which is not a $K(\pi, 1)$, and whose π_1 is $\simeq \mathbb{Z}/2\mathbb{Z}$.

$G \simeq \mathrm{GP}(1, \mathbb{C})$

We are going to use this corollary to determine the structure of $\widetilde{U}_{g,\nu}$ (as a Galois covering of $U_{g,\nu}$) for the "abelian" cases. Let us note for this that

[scan 218]

[p. 109] d1

the inclusion $G \subset A^\circ_{g,\nu}$ induces an inclusion $G_0 \hookrightarrow B_{g,\nu}$, where d3

$$G_0 = G \cap B_{g,\nu} = \text{stabilizer of } a_{g,\nu} \text{ in } G. \tag{40}$$

and as

$$G/G_0 \xrightarrow{\sim} A^\circ_{g,\nu}/B_{g,\nu} \simeq U_{g,\nu}$$

(G being transitive on $U_{g,\nu} = U$) we find that the fact that $G \longrightarrow A^\circ_{g,\nu}$ is a homotopy equivalence, is equivalent to $G_0 \longrightarrow B_{g,\nu}$ being one. Now in all the cases considered, G_0 is already connected: it is reduced to 1 in the cases $(1,0)$ and $(0,2)$, [so in this case the corollary is equivalent to the contractibility of $B_{g,\nu}$], and it is $\simeq \mathbb{C}^*$ in the case $(0,1)$, finally it is $\mathrm{Aff}(1,\mathbb{C})$ in the case $(0,0)$. So we find 217

Apparatus for this scan

140-2-s218-D001 *deletion. Manuscript:* 1) Case $(g,\nu) = (1,0)$: elliptic surface $\simeq \mathbb{U} \times \mathbb{U}$ with 0 holes, so $\pi_1(U_{g,0}) \simeq \mathbb{Z} \times \mathbb{Z}$. In fact, I say that we even have in this case $B_{g,\nu} = B^\circ_{g,\nu} = A^\circ_{g,\nu+1}$ i.e. $B_{g,\nu} = B_{1,0}$ is connected.
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

140-2-s218-D003 *deletion. Manuscript:* [illeg. 1]
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 219]

Corollary. In the abelian cases $2g + \nu < 3$ (and only in those, of course) $B_{g,\nu}$ is connected (i.e. $= A^\circ_{g,\nu+1}$), i.e. $A^\circ_{g,\nu}/A^\circ_{g,\nu+1} \longrightarrow U_{g,\nu}$ is a homeomorphism. So $A^\circ_{g,\nu}/A^\circ_{g,\nu+1} \longrightarrow U_{g,\nu}$ makes the left-hand side a universal covering of $U_{g,\nu}$ iff (g,ν) is distinct from the two pairs $(1,0)$ and $(0,2)$.

Let us therefore assume $(g,\nu) \neq (1,0),(0,2)$ (morally we are working in the anabelian cases, the d1 included abelian cases $(0,1)$ and $(0,0)$ being d2 of no interest for what is to follow, it seems to me). Let us take up diagram (31) again, where in the second row the quotient group $B_{g,\nu}/B^\circ_{g,\nu}$ is therefore identified with:

$$\Pi_{g,\nu} = \pi_1(U_{g,\nu}, a_{g,\nu}).$$

We therefore find

Theorem. Suppose $(g,\nu) \neq (1,0)$ and $(0,2)$,i1 (the subgroup $A_{g,(\nu,\nu+1)}/A^\circ_{g,\nu}|A^\circ_{g,\nu+1}$ of the group $= \Gamma'_{g,\nu+1}$ i2 of Teichmüller

$$\Gamma_{g,\nu+1} = A_{g,\nu+1}/A^\circ_{g,\nu+1}$$

formed of the elements that fix $a_{g,\nu}$ i3 admits a composition series of length 3i4, whose successive factors are $\mathfrak{S}_\nu|\mathfrak{S}_{\nu+1}$ d3, $\Gamma^!_{g,\nu}$ and $\Pi_{g,\nu}$ — deduced from a structure 218

[scan 220]

[p. 110] of extension on $\Gamma^{!}_{g,\nu+1}$

$$1 \longrightarrow \Pi_{g,\nu} \longrightarrow \Gamma^{!}_{g,\nu+1} \longrightarrow \Gamma^{!}_{g,\nu} \longrightarrow 1. \tag{41}$$

[The outer operations of $\Gamma^{!}_{g,\nu}$ on $\Pi_{g,\nu}$ are those deduced by passage to the quotient from those of $A^{!}_{g,\nu} \subset \mathrm{Aut}(U_{g,\nu})$[i1] operating[i2] by outer automorphisms on $\Pi_{g,\nu} = \pi_1(U_{g,\nu}, a_{g,\nu})$.

Another way of saying things is this. Let us distinguish, in $\Gamma_{g,\nu+1}$ operating on $S_{\nu+1}$ [d1] ($\simeq I_{\nu+1}$), the stabilizer of the last element $a_{g,\nu}$, i.e. of its complement, namely $\Gamma'_{g,\nu+1}$ $\simeq A_{g,(\nu,\nu+1)}/A^{\circ}_{g,\nu+1}$[i3], this|the subgroup of index $\nu+1$, inverse image of $\mathfrak{S}_{\nu}$ of $\mathfrak{S}_{\nu+1}$[i4] under $\Gamma_{g,\nu+1} \longrightarrow \mathfrak{S}_{\nu+1}$.

This being so, we have an evident homomorphism of discrete groups, deduced from the inclusion [d2] $A_{g,(\nu,\nu+1)} \hookrightarrow A_{g,\nu+1}$:

$$\Gamma'_{g,\nu+1} \longrightarrow \Gamma_{g,\nu} \tag{42}$$

m341

Marginal note. [m341] N.B. This homomorphism still makes sense without conditions on (g,ν) and it is an isomorphism in the abelian case $2g+\nu \leq 2$.

and this homomorphism is surjective (without conditions on (g,ν)), finally (for $(g,\nu) \neq (1,0),(0,1)$) its kernel is canonically isomorphic to $\Pi_{g,\nu}$, so that we have an extension N.B.

$$1 \longrightarrow \Pi_{g,\nu} \longrightarrow \Gamma'_{g,\nu+1} \longrightarrow \Gamma_{g,\nu} \longrightarrow 1, \tag{43}$$

N.B. [d3]

Scans 221–230

[scan 221]
d1

if|where the corresponding outer operations of $\Gamma_{g,\nu}$ on $\Pi_{g,\nu}$ are those deduced by passage to the quotient from those of [d2] $A_{g,\nu} \simeq \mathrm{Aut}(U_{g,\nu})$ on $\pi_1(U_{g,\nu}, a_{g,\nu}) = \Pi_{g,\nu}$.

The extension structure (41) is deduced from (41)|(43) by inverse image under the inclusion

$$\Gamma^{!}_{g,\nu} \longrightarrow \Gamma_{g,\nu}.$$

Suppose we are in the anabelian case $2g+\nu \geq 3$. As for every extension structure by a kernel with trivial center, there is a canonical homomorphism into the canonical extension structure associated to $\Pi_{g,\nu}$

$$(44) \qquad \begin{array}{ccccccccc} 1 & \to & \Pi_{g,\nu} & \hookrightarrow & \Gamma'_{g,\nu+1} & \longrightarrow & \Gamma_{g,\nu} & \longrightarrow & 1 \\ & & \| & & \downarrow & & \downarrow & & \\ 1 & \to & \Pi_{g,\nu} & \to & \mathrm{Aut}(\Pi_{g,\nu}) & \to & \mathrm{Autext}(\Pi_{g,\nu}) & \to & 1 \end{array}$$

[d3] where the central vertical arrow [d4] is obtained by associating to $g \in \Gamma'_{g,\nu+1}$ the restriction to $\Pi_{g,\nu} \subset \Gamma'_{g,\nu+1}$ of the inner automorphism $\mathrm{int}(g)$. [p. 220]

Theorem well knownIn the anabelian case* $(2g+\nu \geq 3)$[i1]

$$\Gamma_{g,\nu} \xrightarrow{\sim} \mathrm{Autext}_{\mathrm{lac}}(\Pi_{g,\nu}),$$

Which amounts to the same, by (44)[i2]

$$\Gamma'_{g,\nu+1} \xrightarrow{\sim} \mathrm{Aut}_{\mathrm{lac}}(\Pi_{g,\nu}).$$

the image of $\Gamma_{g,\nu} \longrightarrow \mathrm{Autext}\,\Pi_{g,\nu}$ consists of the outer automorphisms which respect the loop structure of $\Pi_{g,\nu}$ of type g,ν.
m345

Marginal note. [m345] * N.B. In fact this remains true [d5] for the pair|case $(1,0)$ (cf. below) and even in the case $(0,2)$ if we define ad hoc the notion of group with loops $(0,2)$.

[scan 222]

[p. 111] (vacuous condition if $\nu = 0$, for that matter…).

Corollary In the anabelian case $(2g+\nu \geq 3)$, the functor $X \longmapsto \pi_1(X)$ from the isotopic[i1] category of surfaces of type g, ν to the outer groups with loops of type (g, ν), is an equivalence of categories, as is the functor $(X, s) \longmapsto \pi_1(X, s)$ from the isotopic category[i2] of pointed|punctured surfaces of type (g, ν), to the groups with loops of type (g, ν).

m346

Marginal note. m346 N.B. The arrows in the|the isotopic category are the isotopy classes of homeomorphisms.

m347

Marginal note. m347 It is even an equivalence at the level of ∞-isotopic categories which expresses only the fact that d1 $A^0_{g,\nu}$ and $A^0_{g,\nu+1}$ are contractible.

It remains to examine to what extent we can adapt these results to the "abelian" case. d2 Let us recall[i3] that in this case, we have

$$(45) \qquad \Gamma'_{g,\nu+1} \xrightarrow{\sim} \Gamma_{g,\nu} \qquad \begin{array}{l}\text{if } 2g+\nu \leq 2 \\ \text{("abelian" cases)}\end{array}$$

thus $\Gamma_{g,\nu}$ identifies with the subgroup of $\Gamma_{g,\nu+1}$ formed by the elements which fix $a_{g,\nu}$.

1) Case $g = 1$, $\nu = 0$ thus $\Gamma_{1,0} \simeq \Gamma'_{1,1} = \Gamma_{1,1}$.

Let us consider the canonical homomorphism

$$(46) \qquad \Gamma_1 = \Gamma_{1,0} \longrightarrow \mathrm{Autext}(\Pi_{1,0}) = \mathrm{Aut}(\Pi_{1,0})$$

$$(\simeq \mathrm{Gl}(2, \mathbb{Z}) \text{ when we have chosen a basis of } \Pi_{1,0} \simeq \mathbb{Z}^2)$$

which corresponds to the homomorphism

$$(46 \text{ bis}) \qquad \Gamma_{1,1} \longrightarrow \mathrm{Aut}\, \pi_1(U_{1,0}, a_{1,0}) \qquad (\simeq \mathrm{Gl}(2, \mathbb{Z})),$$

deduced both of them[i4] by passage to the quotient from the d4 obvious operations of $A_1 = A_{1,0}$= $\mathrm{Aut}(X_1)$[i5], and of [p. 221]

$A_{1,1} = \mathrm{Aut}(X_{1,1}|U_{1,1}, a_{1,0})$. It is immediate that this homomorphism is surjective, but less obvious that it is an isomorphism, i.e. that every homeomorphism of X_1 which induces the identity [d1] the [d2] Π_1 is isotopic[i1] [d3] to the identity — this is nevertheless a true (and known) result.

In the present case where [d4] X_1 [d5] identifies[i2] with the underlying topological space of a topological group H (which is the case in all the abelian cases except that of $g = 0$, $\nu = 0$ of the 2-sphere) [d6], by translations|translation we have a natural homomorphism

$$(47) \qquad H \longrightarrow A_{g,\nu} \simeq \mathrm{Aut}_{\mathrm{top}}\, H$$

allowing us to identify H with a topological[i3] subgroup of $A_{g,\nu}$, and we find that the map

$$(48) \qquad (g, u) \longmapsto gu \qquad H \times \underbrace{A_{g,\nu+1}}_{\substack{\text{Stabilizer}\\ \text{of } 1_H \text{ in}\\ \longleftarrow A_{g,\nu} \simeq \mathrm{Aut}_{\mathrm{top}}(H)}} \longrightarrow A_{g,\nu}$$

is a homeomorphism. [d7] This [d8] gives (45) again (since H is connected) [p. 222]

[p. 112] and makes it considerably more precise, by

$$\pi_i(A_{g,\nu+1}) \simeq \pi_i(A_{g,\nu}) \times \pi_i(H) \qquad (49)$$

[d1] Non-spherical abelian cases, i.e. any|only of the three cases $(g = 1, \nu = 0)$, $(g = 0, \nu = 1)$, $(g = 0, \nu = 2)$.

In the "limiting" cases $(1, 0)$ and $(0, 2)$ (when (g, ν) is abelian, $(g, \nu + 1)$ anabelian), since $A^0_{g,\nu} \simeq H \times A^0_{g,\nu+1}$ with $A^0_{g,\nu+1}$ contractible, we find again that $H \longrightarrow A^0_{g,\nu}$ is a homotopism, [d2]

(Let us note that in the cases envisaged$(1, 0)$, $(0, 2)$ and $(0, 1)$[i1], if we choose a complex structure on the|the pure compactification $\widehat{X}$ of $X = U_{g,\nu}$ and choose $a_{g,\nu}$ as origin, there is a unique $\mathbb{C}$-algebraic group structure on $\widehat{X}|X$ admitting 1 as unit, and [d3] the[i2] [d4] identity component of the group of automorphisms of the algebraic variety X is precisely none other than the group of translations, in the limiting cases $(1, 0)$ and $(0, 2)$. [scan 225]

2) Case $g = 0$, $\nu = 2$, thus $H \simeq \mathbb{C}^*$,

$$A_{g,\nu|2} \simeq H \times A_{g,\nu+1} \quad \text{i.e.} \quad A_{g,2} \simeq \mathbb{C}^* \times \underline{A_{g,3}}$$

thus

$$(50) \qquad \begin{cases} \Gamma_{g,2} \simeq \Gamma'_{g,3} \\ A^0_{g,2} \overset{\simeq}{\leftarrow} \mathbb{C}^* \quad \text{(homotopy equivalence)} \end{cases}$$

[d1] $\Pi_{①,2} \simeq \mathbb{Z}$[d2], let us consider (rather $\Pi_{0,2}$)

$$(51) \qquad \Gamma_{g,2} \overset{\rho}{\to} \mathrm{Aut} \begin{pmatrix} \Pi_{①,2} \\ \| \\ \pi_1(U_{0,2}) \end{pmatrix} \simeq \{\pm 1\} \simeq \mathfrak{S}_2$$

identifying with

$$(52) \qquad \Gamma'_{g,3} \longrightarrow \mathrm{Aut} \begin{pmatrix} \Pi_{①,2} \\ \| \\ \pi_1(U_{0,2}, a_{0,2}) \end{pmatrix} \simeq \{\pm\}$$

This time the homomorphism (51) is <u>not</u> bijective — it identifies with the canonical homomorphism

$$(51 \text{ bis}) \qquad \Gamma_{g,2} \overset{\rho}{\to} \mathfrak{S}_2$$

with kernel $\Gamma^!_{g,2}$ — and $\Gamma^!_{g,\nu|2}$ is not reduced to 1, for example (if we take $U_{0,2} = \mathbb{C}^*$)

$z \longrightarrow \overline{z}$ defines an element of $\Gamma^!_{g,2}$ which is not equal to 1. Let us note [d6] now[i2] the canonical homomorphism (defined without restriction on (g, ν)) [p. 224]

[scan 226]

[p. 113]

$$(53) \qquad \Gamma_{g,\nu} \xrightarrow{\chi} \{\pm 1\}$$

m349

Marginal note. m349 This homomorphism is always surjective. We shall denote its kernel by $\Gamma^+_{g,\nu}$ (and no longer[i1] $\Gamma^0_{g,\nu}$!).

via the action of $\Gamma_{g,\nu}$ on the orientation module $T_g = T$ of $U_{g,\nu}$ [d1] (which is defined, for $(g,\nu) \neq (0,0),(0,1)$, $(0,2)$[i2], in terms of the loop structure of $\Pi_{g,\nu}$). In the present case, putting together ρ and $\rho|\chi$, we find a homomorphism

$$(54) \qquad g \longmapsto (\rho(g), \chi(g)) : \quad \Gamma_{g,2} \longrightarrow \mathfrak{S}_2 \times \{\pm 1\} \simeq (\pm 1) \times (\pm 1)$$

which is obviously surjective (if g corresponds to $z \longmapsto z^{-1}$, its image is $(-1,-1)|(-1,1)$, if it corresponds to $z \longmapsto \overline{z}$, its image is $(1,-1)$).

m350

Marginal note. m350 N.B. This suggests that for an isotopic description of the category of surfaces X of type[i3] $(0,2)$, we must use the pair of $\pi_1(X)$ $(\simeq \mathbb{Z})$ and its orientation module T; likewise|ditto below concerning the cases of types|the case of type $(0,1)$, but then $\pi = 0$ and T suffices.

I say that it is bijective, [d3] $\Gamma_{g,2} \xrightarrow[\rho,\chi]{\sim} \mathfrak{S}_2 \times \pm 1$[i4] which amounts to the same, that the restriction of ρ (51 bis) to the kernel $\Gamma^+_{0,2}$[i5] of $\chi : \Gamma_{g,2} \longrightarrow \{\pm 1\}$ is an isomorphism, or what amounts to the same

Theorem (well known!)

$$\Gamma^{!+}_{0,2} = 1, \tag{55}$$

or again: $\rho^{+}_{0,2} : \Gamma^{+}_{0,2} \longrightarrow \mathfrak{S}_2$ is an isomorphism, or $\chi^{!}_{0,2} : \Gamma^{!}_{0,2} \xrightarrow{\sim} \pm 1$.

[N.B. If we want a statement common to the [d4] two "limiting abelian" cases $(1,0)$ and $(0,2)$, we shall say that in these cases, $\Gamma^{+}_{g,\nu} \longrightarrow \mathrm{Aut}(\Pi)$ [p. 225]

and taking into account that the identity component $A^0_{0,3}$ of $A^!_{0,3}$ is contractible, we indeed find again[i1] that (59) is an [d1] of homotopism.

Common conclusion to all cases.[i2] It is appropriate to include in the notion of "group with loops" also the four[i3] abelian cases, and we do so as follows:

1) Type $(1,0)$ — we do not have to supplement the general definition, which here amounts to saying that[i4] Π is an abelian group, a free $\mathbb{Z}$-module of rank 1|2. Its orientation module T can indeed be defined as $H_2(\Pi,\mathbb{Z})$, or as $\Lambda^2_{\mathbb{Z}}\Pi$. The [d2] sign[i5] of an automorphism of Π is given|given by its action on T, it is also its determinant.

2) Type $(0,2)$, $\Pi \overset{\text{not canonical}}{\simeq} \mathbb{Z}$. Here we must give ourselves, in addition to Π, an invertible $\mathbb{Z}$-module T, and the loop structure is defined by one of the two isomorphisms $T \simeq \mathbb{Z}$. An automorphism of the loop structure is therefore defined by [d3] (any[i7] pair [d4] u_Π, u_T of an automorphism of Π and one of T. [p. 228]

[scan 231]

the extension of this group by the said Π_1 !

What is wrong, one senses it well enough, is the fact that this equivalence of categories, is $1|0$-isotopic(i.e. takes into account the Π_0 of the spaces of homeomorphisms)[i1], but neglects the internal topological[i2] structure of the topological spaces [d1] Homéo(X, X'), which one brutally replaces by their Π_0 — neglecting the homotopy structure of the connected components, which are (as torsors under topological groups $\simeq A^\circ_{g,\nu}$) homeomorphic to $A^\circ_{g,\nu}$. It is [d2] in the anabelian case, and in that case only, that this group is ∞-connected. In the abelian case, experience proves that, the preceding description must be replaced by Ladegaillerie's in terms [d3] $B_{D^*} \longrightarrow B_u$ or $\Pi_{D^*} \longrightarrow \Pi_u$, [d4] it then becomes in all cases $\neq (0,0)$[i3] ∞-faithful (i.e. takes into account the $\Pi_i(A^\circ_{g,\nu})$). The only case [m353]

Marginal note. [m353] N.B. There is no [illeg. 1] k here — [illeg. 2] $T|J$ is described intrinsically from the structure of topoi or of groupoids

A digression !

20 2-isotopic description of the category of topological spheres

Here is a way to find a 1-isotopic description (and even 2-isotopic, as it happens) by using a canonical covering group [i1] $\widetilde{A}_0$ of A_0 [d1], fitting into the exact sequence

$$(62) \qquad 1 \longrightarrow \underset{\underset{\{\pm 1\}}{\|}}{\mu_2(\mathbb{C})} \longrightarrow \widetilde{A}_0 \longrightarrow A_0 \longrightarrow 1,$$

which contains the [d2] corresponding exact sequence of subgroups

$$(63) \qquad 1 \longrightarrow \mu_2 \longrightarrow \widetilde{\mathrm{Sl}}(2,\mathbb{C}) \longrightarrow \widetilde{\mathrm{GP}}(1,\mathbb{C}) \longrightarrow 1$$

where $\widetilde{\mathrm{Sl}}(2,\mathbb{C})$ is made up of the $\frac{1}{2}$-linear automorphisms, of $\mathbb{C}^2$ (for an unspecified $\mathbb{R}$-automorphism ρ[i2], id or complex conjugation τ), such that the corresponding ρ-linear automorphism of $\bigwedge^2 \mathbb{C}^2 \simeq \mathbb{C}$ is the identity if $\rho = \mathrm{id}$, and is $\tau : z \longrightarrow \bar{z}$ if $\rho = \tau$ (i.e., independently of the|of the case, [d3]one considers[i3] a unimodular vector space V over $\mathbb{R}$, whence $V_{\mathbb{C}}$ over $\mathbb{C}$, with a restriction of $\bigwedge^2 V_{\mathbb{C}}$ to $\mathbb{R}$, whence|thus a complex conjugation on $\bigwedge^2 V_{\mathbb{C}}$ — and a [d4] basis of $\bigwedge^2 V_{\mathbb{C}}$ invariant under this — and one is interested in the $\rho|\mathbb{R}$-linear ($\rho \in \mathrm{Aut}_{\mathbb{R}}\mathbb{C}$) automorphisms of $V_{\mathbb{C}}$ which on $\bigwedge^2 V_{\mathbb{C}}$ are id or complex conjugation …) 232

[p. 117] $\widetilde{\mathrm{GP}}(1,\mathbb{C})$ identifies with the group of conformal automorphisms [d1] of the Riemann sphere [d2] $\mathbb{P}^1_{\mathbb{C}} \simeq \mathbb{P}^1(\mathbb{C}^2)$, or automorphisms of $\mathbb{P}^1_{\mathbb{C}}$ as an $\mathbb{R}$-scheme. We choose here|let act on $X_0 = \mathbb{P}^1_{\mathbb{C}}$, so that we have a canonical inclusion

$$\widetilde{\mathrm{GP}}(1,\mathbb{C}) \longrightarrow A_0 \qquad (64)$$

which is (by what precedes (59)) is a homotopy equivalence. Unless I am mistaken it follows (unless I am mistaken)[i1] that the classification of extensions of the topological group A_0[i2] by a group discrete|say μ is equivalent, by the restriction functor, to the category of corresponding extensions for [d3] $\mathrm{GP}(1,\mathbb{C})$, which makes it possible to construct $\widetilde{A}_0$, up to unique isomorphism. This being so, the datum of a surface compact oriented X[i3] of genus 0, which is equivalent to that of a torsor [Isom($\mathbb{P}^1_{\mathbb{C}}, X$))|(Isom($\mathbb{P}^1_{\mathbb{C}}, X$)) under A_0, defines 1°) the torsor under (± 1) deduced from it by $\chi : A_0 \longrightarrow \{\pm 1\}$ (which is surjective, with kernel A_0°) and φ 2°) of the [m359]

Marginal note. [m359] N.B. $\widetilde{\mathrm{GP}}(1,\mathbb{C})$ is also the group of $\mathbb{R}$-linear automorphisms of the $\mathbb{R}$-algebra $M_2(\mathbb{C})$ [d4] (and the ∞-isotopic classification of 2-spheres is therefore equivalent to that of simple algebras of rank 4 over [d5] a not specified quadratic extension of $\mathbb{C}$…) 233

[scan 235]

groupoid of liftings of this [d1]A_0[i1] torsor to an $\widetilde{A}_0$-torsor, which is a connected groupoid (= gerbe) banded by the abelian band[i2] $\underbrace{\mu_2(\mathbb{C}) = (\pm 1)}_{\mu}$, and in which consequently $\mathrm{Tors}(\mu) \simeq \mathrm{Ens}_2$[i3] operates (it is a 1-torsor under the group-category $\mathrm{Tors}(\mu)$). Thus associating to every X the pair $(\omega, \mathcal{R})$ of the associated μ-torsor ω (i.e. the 2-element set of the two orientations of X, or what amounts to the same, the module of orientations of X), plus the μ-[i4]groupoid $\mathcal{R}$, one finds a 2-functor from the 2-isotopic 2-category of topological 2-spheres, to the 2-category of pairs $(\omega, \mathcal{R})$, and this is an equivalence of 2-categories (from this point of view one feels like saying that it is 3-faithful, but since [d2] essential surjectivity on objects is trivial, the name 2-faithful is better, and even (since in describing it we took care to preserve, 234

[scan 236]

[p. 118] the Π_1 (in addition to the Π_0)[i1] of the connected components of the (A_0-torsors)[i2] $\mathrm{Isom}(X_0, X)$, which are A_0°-torsors thus with Π_1 Isomorphic|isomorphic to $\mu = \{\pm 1\}$, it is even better to call it 1-faithful — but in fact it is even 2-faithful (in the corresponding sense) thanks to the fact that

$$(65)\quad \Pi_2(A_0^\circ) \xleftarrow{\sim} \Pi_2(\mathrm{GP}(1,\mathbb{C})) \xleftarrow{\sim} \Pi_2(S^3/\pm 1) \wr \Pi_2(S^3) = 0$$

On the other hand it is not 3-faithful, for

$$(66)\qquad \Pi_i(A_0^\circ) \xleftarrow{\sim} \Pi_i(S^3) \qquad \text{for } i \geq 2$$

and $\Pi_3(S^3) \simeq \mathbb{Z} \neq 0$ hence $\Pi_3(A_0^\circ) \simeq \mathbb{Z} \neq 0$,

We are looking for an ∞-isotopic description, which takes into account the homotopy groups of all orders (to be determined !) of A_0° i.e. of S^3 (or again, of $\mathrm{Sl}(2,\mathbb{C})$, or of $\mathrm{GP}(1,\mathbb{C})$. Up for competition ! 235

[scan 237]

[p. 119] But already for the modest description proposed, with pretensions to being[i1] 1 or 2-isotopic, for lack of having written things carefully, I am not too sure whether the description given is really correct — I am a little worried by the fact that I have not [d1]imposed[i2] any [d2] relations between the μ-[i3]torsor ω, and the μ-groupoid $\mathcal{R}$. More generally let G be a topological group ($\widetilde{A}_0$, or $\widetilde{\mathrm{GP}}(1,\mathbb{C})$),

topological group G

such that [d3]G°[i4] is simply connected; [d4] [d5]

$$(67)\qquad \Pi_1(G^\circ) = 0$$

let

$$(68)\qquad \mu = \mathrm{Centre}(G^\circ), \qquad \Gamma = G/G^\circ$$

m363

Marginal note. m363 we assume μ discrete (thus G° identifies with the universal covering group of $G^\circ/\mu = \mathcal{H}^\circ$ (if $\mathcal{H} = G/\mu$))

then the topological group extension G of Γ by G° defines

$$(69) \qquad \Gamma \longrightarrow \mathrm{Aut}\,\mathrm{ext}(G^\circ) \qquad (\longrightarrow \mathrm{Aut}(\mu).)$$

and the set of classes of extensions corresponding to a given outer[i5] operation of Γ on G° is in a natural way a torsor under $H^2(\Gamma, \mu)$ (if it is not empty, which is|we have excluded by the starting hypothesis, starting from G…) 236

[scan 238]

This category of extensions is moreover equivalent d1 to that of splittings of a certain group-category defined by Sinh via (69)[i1], whose Π_0 and Π_1 are respectively Γ and μ — which is thus[i2] here split by the datum of the extension G. (In the case that interests us, $\Gamma \simeq \mu \simeq \{\pm 1\}$, and this extension is even split, and corresponds to an operation of order 2 of Γ on G°, which I very much doubt is an inner automorphism. In fact, I have the impression that in the two cases we are dealing with ($\widetilde{\mathrm{GP}}(1, \mathbb{C})$ and $\widetilde{A}_0$) that (69) is an isomorphism $\Gamma = \{\pm 1\} \xrightarrow{\sim} \mathrm{Autext}(G^\circ$

This being so, the datum of a torsor under $\mathcal{H} = G/\mu$ defines 1°) a torsor under Γ, $\mathcal{H} \longrightarrow \Gamma \simeq \mathcal{H}/\mathcal{H}^\circ$; 2°) the groupoid of liftings of liftings of this torsor to a torsor under G, which is a connected[i3] μ-groupoid (on which μ operates). m365

Marginal note. m365 We assume that Γ operates trivially on μ i.e. $\mu \subset \mathrm{Centre}(G)$

If we d3 take this up again in terms of bundles over a base space S we find 237

[scan 239]

[p. 120] again on S (for every topological $\mathcal{H}_S$-torsor) a pair $(\omega, \mathcal{R}|R)$ of a Γ-torsor, and of a μ-gerbe on S, which are described (up to isomorphism [illeg. 1] equivalence[i1] up to equivalence|and equivalence) by $H^1(S,\Gamma)$ and $H^2(S,\mu)$ respectively. We would like to isolate conditions on G and on S[i2] for the map

$$H^1(S,\mathcal{H}) \longrightarrow H^1(S,\Gamma) \times H^2(S,\mu) \tag{70}$$

to be bijective. m367

Marginal note. m367 N.B. ω does not depend on the choice of the extension $\widetilde{G}$ of $\mathcal{H}$ by $\mathfrak{z}|\zeta \simeq \Pi_1(\mathcal{H}^\circ)$; on the other hand $\mathcal{R}$ depends on it (and one would have to see how)

Injectivity : If the image of a $\zeta \in H^1(S,\mathcal{H})$,[i3] in $H^2(S,\mu)$ is zero, the element of $H^1(S,\mathcal{H})$ lifts to an element $\tilde{\zeta}$ of $H^1(S,\widetilde{\mathcal{H}} = G)$; whose image in $H^1(S,\Gamma)$ under $G \longrightarrow \Gamma$ is the same as that of ζ, so if it is trivial, one sees that $\tilde{\zeta}$ comes from a $\tilde{\zeta}_0 \in H^1(S,G^\circ)$. If we know that $H^1(S,G^\circ) = (1)$, we win. By the sledgehammers of homotopy, it works if $\exists n \in \mathbb{N}$ with

$$\Pi_i(G^\circ) = 0 \quad \text{if} \quad i \leq n$$

(thus $\Pi_i(B_{G^\circ}) = 0$ if $i \leq n+1$)[i4] d1 d2 S a CW-complex of dimension $\leq n+1$ m368

Marginal note. m368 in the case we are dealing with, one can take $n = 2$

For surjectivity, note that for|first an 238

element of $H^2(S, \mu)$, the obstruction to its lifting to an element ζ[i1] of $H^1(S, \mathcal{H})$ is in $H^2(S, G)$ [by the associated exact sequence of cohomology : $1 \longrightarrow \mu_S \longrightarrow G_S \longrightarrow \mathcal{H}_S \longrightarrow 1$] one must express that a certain [d1] gerbe banded by G_S is neutral — brr!. But let us rather start from the element $\omega|\tilde{\zeta}$[i2] of $H^1(S, \Gamma)$, if the extension of Γ by [d2]$\mathcal{H}^\circ$ is split, then one can find a $\zeta_0 \in H^1(S, \mathcal{H}_S)$ which gives rise to ω. It has a certain obstruction ρ_0 in $H^2(S, \mu)$, and it is a matter of correcting ζ_0 to ζ, in[i3] such a way that the obstruction becomes the given $\rho \in H^2(S, \mu)$. [d3] Using ζ_0[i4] to twist $\mathcal{H}_S$ into $\mathcal{H}'_S$, and (via the operation of $\mathcal{H}_S = G_S/\mu_S$[i5] on G_S, taking into account that $\mu_S \subset \operatorname{centre} G_S$) to twist G_S also into G'_S[i6], whence

$$1 \longrightarrow \mu \longrightarrow G'_S \longrightarrow \mathcal{H}'_S \longrightarrow 1$$

one finds that the ζ having the same image in $H^1(S, \Gamma)$ 239

[p. 121] that ξ_0 correspond $1-1$[i1] to the $\xi' \in H^1(S, \mathcal{H}'_S)$.

For such a [d1] ξ', let $\delta'(\xi') \in H^2(S, \mu)$ be the obstruction to lifting it to $H^1(S, \mathcal{G}'_S|\mathcal{G}_S)$, and $\delta(\xi') = \delta(\xi)$ the obstruction to lifting it to $H^1(S, \mathcal{G}_S)$. Unless I am mistaken one has

$$\delta'(\xi') = \delta(\xi') - \rho_0$$

i.e.

$$\delta(\xi') = \delta(\xi) = \delta'(\xi') + \rho_0$$

and one wants $\delta(\xi) = \rho$ i.e.

$$\delta'(\xi') = \rho - \rho_0$$

and the question again comes down to [d3] the[i2] surjectivity of $H^1(S, \mathcal{H}'_S) \longrightarrow H^2(S, \mu)$ [d4] — I am not getting anywhere. One ought to consult competent people, like Giraud or Larry Breen. One feels that one ought to work with a Gr-stack $\underline{\underline{\mathcal{H}}}$ of coefficients, with invariants $\underline{\pi}_0 \simeq \Gamma$ and $\underline{\pi}_1 \simeq \mu$, (but not necessarily a Picard stack!) [d5] and $H^1(S, \underline{\underline{\mathcal{H}}}) \simeq$ Classes of maps from S to $B\underline{\underline{\mathcal{H}}}$, which is a connected space with $\pi_1(B\underline{\underline{\mathcal{H}}}) \simeq \Gamma$, $\pi_2(B\underline{\underline{\mathcal{H}}}) = \mu$. Here the Postnikoff class in $H^3(\Gamma, \mu)$ is zero, 240

[scan 242]

[but perhaps there is no reason to cling too much to this hypothesis, corresponding to the existence of an extension[i1] $\mathcal{G}$ of $\mathcal{H}$ by $\pi_1(\mathcal{H}^\circ)$[i2] [d1] which gives back the universal extension of $\mathcal{H}^\circ$ by $\pi_1(\mathcal{H}^\circ)$] one has a homomorphism $B\mathcal{H}$ [d2] $\longrightarrow B\underline{\underline{\mathcal{H}}}$ which induces an isomorphism for the

π_i for $i \leq 2$, and for $i \leq n$ (where $n \geq 2$ is given[i3]) iff $\pi_i(B\mathcal{H}) = 0$ for $2 < i \leq n$, i.e. $\pi_i(\mathcal{H}) = 0$ for $2 \leq i \leq n-1$ [in the case we are interested in $\mathcal{H} = A_0$, one can take $n = 3$). This implies that for every C-W-complex S of dimension $\leq n$, one has (Hot denoting the morphisms in the unpointed homotopy category)[i4]

$$\mathrm{Hot}(S, B\mathcal{H}) \xrightarrow{\sim} \mathrm{Hot}(S, B\underline{\underline{\mathcal{H}}})$$

i.e.|i.e.

$$H^1(S, \mathcal{H}) \xrightarrow{\simeq} H^1(S, \underline{\underline{\mathcal{H}}})$$

But if the Postnikoff-Sinh invariant $K|k \in H^3(\Gamma, \mu)$ is zero, [d4] (as well as the action of Γ on μ) then unless I am mistaken $B\underline{\underline{\mathcal{H}}}$ is identified with a product $K(\Gamma, 1) \times K(\pi, 2)$, [d5] (this "identification" depending precisely on the 241

[scan 243]

[p. 122] choice of the $H^2(\pi_1, \pi_2) \simeq H^2(\Gamma, \mu)$!), and hence

$$H^1(S, \underline{\underline{\mathcal{H}}}) \xrightarrow{\simeq} H^1(S, \Gamma) \times H^2(S, \mu)$$

for every space S, hence for S a C-W-complex of dimension $\leq n$

$$(71) \qquad H^1(S, \mathcal{H}) \xrightarrow{\simeq} H^1(S, \Gamma) \times H^2(S, \mu)$$

So the classification of bundles of topological spheres over a topological space S, for a C-W complex S of dimension ≤ 3, really does work. Of course, the fact that one is obliged here to

restrict oneself to [d1] S of dimension ≤ 3 is due to the fact that we have found [d2] (via $\underline{\underline{\mathcal{H}}}$) only a 2-isotopic (and not ∞-isotopic) description of the category of topological 2-spheres.

I would like to take up the classification again for an arbitrary CW-complex S, using the fact that the inclusion

$$\widetilde{\mathrm{GP}}(1,\mathbb{C}) \hookrightarrow A_0$$

is a homotopy equivalence, and therefore induces a bijection

$$H^1(S, \widetilde{\mathrm{GP}}(1,\mathbb{C})) \longrightarrow H^1(S, A_0)$$

and even an ∞-equivalence of the ∞-categories of [d1] torsors[i1] over S, with [d2] groups $\widetilde{\mathrm{GP}}$ (corresponding to bundles of conformal spheres, or of projective lines over an [d3] $\mathbb{R}$-algebra (unspecified)[i2] isomorphic to $\mathbb{C}$) and with group A_0 — corresponding to sphere bundles over S.

The first invariant of a bundle with group $\widetilde{\mathrm{GP}}$ is a [d4] torsor $\eta|T$ under $(\mathbb{Z}/2\mathbb{Z})_S$ [d5] defined (up to isomorphism not unique) by a[i3] χ ($\in H^1(S, \mathbb{Z}/2\mathbb{Z})$). [m374]

Marginal note. [m374] i.e. an étale covering|double covering of degree 2. The datum of $\eta|\chi$ amounts to the datum of a system T of twisted integers over S.

This torsor[i4] will serve to twist $\mathbb{C}$ (via the faithful[i5] operation of $\mathbb{Z}/2\mathbb{Z}$ on the $\mathbb{R}$-extension $\mathbb{C}$), [d6] whence a locally [d7] constant bundle of [d8] quadratic[i6] extensions of $\mathbb{R}$ [d9], say C, and one [d10] will enrich S with the sheaf $\underline{C}_S$ (or $\underline{C}$)[i7] of continuous sections of C (which is a way of twisting [d11] $\mathrm{GP}(1,\mathbb{C})_S$ into $\mathrm{GP}(1,C)_S = \mathrm{GP}(1,\underline{C})$)) and the point is to [d12] describe in an understandable way [d13] — passing[i8] if need be, to the [d14] n-isotopic ones, for $n = \ldots$ — the category 243

[p. 123] — depending on the choice of χ via $\underline{C}$ — of Azumaya algebras of rank 4 over $\underline{C}$, or again of bundles of projective lines over $\underline{C}$, or of torsors under $\mathrm{GP}(1, \underline{C})$.

Now using [d1] the exact sequence[i1]

$$1 \longrightarrow \mu_{2S} \longrightarrow \mathrm{Sl}(2, \underline{C}_S) \longrightarrow \mathrm{GP}(1, \underline{C}_S) \longrightarrow 1$$

one associates to an object of the category — say a torsor under $\mathrm{GP}(1, \underline{C}_S)$ — the fibered (over variable open subsets of S)[i2] category of these liftings to $\mathrm{Sl}(2, \underline{C}_S)$, which is a gerbe $\mathcal{G}$[i3] banded by μ_2. It is this gerbe that is the second complete invariant — finer than its class [d2] up to equivalence, which is identified with a[i4] $\xi \in H^2(S, \mu_2) = H^2(S, \{\pm 1\})$ (playing the role of a Brauer group)

An isomorphism of bundles, with invariants $(T, \mathcal{G})$, $(T', \mathcal{G}')$, will define an isomorphism $T \simeq T'$ (whence an isomorphism [d3] $\underline{C}_T \simeq \underline{C}_{T'}$ whence an isomorphism $\mathrm{GP}(1, \underline{C}_T) \simeq \mathrm{GP}(1, \underline{C}_{T'})$) — and an equivalence of gerbes — one should 244

spell out that for two isomorphisms f, g of the torsors, [d1] whence

$$f_T, g_T : T \underset{\sim}{\overset{\simeq}{\underset{\dagger}{\rightrightarrows}}} T' \qquad f_{\mathcal{G}}, g_{\mathcal{G}} : \mathcal{G} \underset{\simeq}{\overset{\simeq}{\rightrightarrows}} \mathcal{G}'$$

and for every homotopy h_t $(0 \leq t \leq 1)$ from f to g, one finds $f_T = g_T$ and an isomorphism $h_* : f_{\mathcal{G}} \xrightarrow{\sim} g_{\mathcal{G}}$ of equivalences of gerbes, which depends only on the homotopy class of this homotopy. One thus finds a 2-functor, from the 2-category of [d3] torsors over S with group $\widetilde{\mathrm{GP}}(1, \mathbb{C})$, to the 2-category formed by pairs $(T, \mathcal{G})$[i1] of a [d4] system[i2] of twisted integers, [d5] ($\Longleftrightarrow$ of a torsor over S with group [d6] $\mathbb{Z}/2$[i3]) and of a [d7] $\mu_2(\mathbb{C})$-gerbe $\mathcal{G}$ over S. This 2-functor, unless I am mistaken, is 2-faithful under the conditions spelled out above ([d8] (dimension $S \leq 4$), and is 3-faithful (i.e. the injective map $H^1(S, \widetilde{\mathrm{GP}}) \longrightarrow |-H^1(S, \mathbb{Z}/2\mathbb{Z}) \times H^2(S, \mu_2)$ is surjective) 245

[scan 247]

[p. 124] if one even has dimension $S \leq 3$. One expects it to be 1-faithful as soon as dimension $S \leq 5$, 0-faithful as soon as dimension $S \leq 6$. [N.B. the assertion[i1] "0-faithful" means that ??
if above[i2] one has two homotopies h, h' from f to g, such that $h_* = h'_*$, then h and h' are homotopic. The condition "1-faithful" means 0-faithful and[i3] that every isomorphism from $f_{\mathcal{G}}$ to $g_{\mathcal{G}}$ [d1] is of the form h_* (with h well determined up to homotopy, by the preceding condition of 0-faithfulness). The 2-faithful condition means that in addition, for[i4] every [d2] [d3] $\varphi : T \simeq T'$, $\psi_{\mathcal{G}} : \mathcal{G} \overset{\approx}{\to} \mathcal{G}'$, there exists an isomorphism of bundles f such that $\varphi = f_T$, [d4] and an isomorphism $\psi \simeq f_{\mathcal{G}}$. Finally 3-faithful means that in addition, for every pair $T, \mathcal{G}$, $\exists\, T', \mathcal{G}'$ coming from a bundle, [d5] and an isomorphism $T \simeq T'$ and an equivalence $\mathcal{G} \cong \mathcal{G}'$. These categorical notions should simply interpret that, if one looks at $\mathcal{H} = \widetilde{\mathrm{GP}}(1, \mathbb{C}) \overset{\alpha}{\to} \underline{\underline{\mathcal{H}}}$ — where $\underline{\underline{\mathcal{H}}}$ is deduced from $\mathcal{H}$ by "killing the homotopy gr°ups π_i for $i \geq 2$", so that 246

21 Connection with Teichmüller spaces.

First a supplement connected with the diagram of inclusions[i1] (31) of number 19, in which $A_{g,(\nu,\nu+1)}$ deserves the simpler notation $A^{\bullet}_{g,\nu}$ (group of automorphisms of $U_{g,\nu}$ pointed at $a_{g,\nu}$). Consider the inclusion|the filtration of subgroups of A_g

$$A^{\circ}_{g,\nu} \supset B_{g,\nu} \supset A^{\circ}_{g,\nu+1} \tag{72}$$

[d1]

giving, on dividing by $A_{g,\nu+1}$ and in the anabelian case $2g+\nu \geq 3$, the fibration (73)

$$\begin{array}{ccc} \widetilde{U}_{g,\nu} & \longrightarrow & U_{g,\nu} \\ \simeq & & \\ A^{\circ}_{g,\nu}/A^{\circ}_{g,\nu+1} & & \end{array}$$

We seek the largest subgroup of A_g that normalizes these|the triple (72), and which [d2] operates[i2] therefore [d3] the fibration $\widetilde{U}_{g,\nu} \to U_{g,\nu}$ (where $\widetilde{U}_{g,\nu}$ is the universal covering of $U_{g,\nu}$ based at $a_{g,\nu}$); since the normalizers of $A^{\circ}_{g,\nu}$ and $A^{\circ}_{g,\nu+1}$ respectively are $A_{g,\nu}$ and $A_{g,\nu+1}$, the group in question must be contained in their intersection $A^{\bullet}_{g,\nu}$, which normalizes [d4] $B_{g,\nu} = A^{\bullet}_{g,\nu} \cap A^{\circ}_{g,\nu}$. It is therefore this group that should be made to operate on the fibration (73) – the subgroup formed [d5] of the elements of $A_{g,\nu}$[i3] whose operation

[scan 252]

on $U_{g,\nu}$ is isotopic to the identity being precisely $B_{g,\nu}$ – so it is the group Γ

$$A^{\bullet}_{g,\nu}/B_{g,\nu} \simeq \Gamma_{g,\nu}$$

that, as it should, operates up to isotopy. We would like to describe the group of all automorphisms of the topological fibration $\widetilde{U}_{g,\nu}$ over $U_{g,\nu}$ which will a priori be an extension of the group

$$\begin{aligned} A_{g,\nu} = \mathrm{Aut}(U_{g,\nu}) \quad \text{by} \quad \Pi_{g,\nu} &= \pi_1(U_{g,\nu}|\widetilde{U}_{g,\nu}, a_{g,\nu}) \\ &= \mathrm{Aut}_{U_{g,\nu}}(\widetilde{U}_{g,\nu}). \end{aligned}$$

d1 This extension is split canonical[ly i1] d2 over $A^{\bullet}_{g,\nu}$, stabilizer at the base point $a_{g,\nu}$ i2 (and we thus recover the operation of $A^{\bullet}_{g,\nu}$ for the fibration (73). Now we already have an extension $\Gamma'_{g,\nu+1}$ of $\Gamma_{g,\nu}$ by $\Pi_{g,\nu}$, whence by inverse image under $A_{g,\nu} \to \Gamma_{g,\nu} = A_{g,\nu}/A^{\circ}_{g,\nu}$, an extension (which I am going to denote by $\widetilde{A}_{g,\nu}$) of $A_{g,\nu}$ by $\Pi_{g,\nu}$:

$$\widetilde{A}_{g,\nu} \simeq A_{g,\nu} \times_{\Gamma_{g,\nu}} \Gamma'_{g,\nu+1} \tag{74}$$

= quotient group of the subgroup d3 $\widetilde{A}^{\natural|\sharp}_{g,\nu}$ of $A_{g,\nu} \times A^{\bullet}_{g,\nu}$ formed of the pairs (u, v), $u \equiv v$ d4 modulo $A^{\circ}_{g,\nu}$, by the subgroup d5 $1 \times A^{\circ}_{g,\nu+1}$.

We thus have two (and = three!)[i3] extension structures on $\widetilde{A}_{g,\nu}$
(75)

$$1 \to \Pi_{g,\nu} \to \widetilde{A}_{g,\nu} \xrightarrow{p} A_{g,\nu} \longrightarrow 1$$

$$1 \to A^{\circ}_{g,\nu} \to \widetilde{A}_{g,\nu} \to \Gamma'_{g,\nu+1} \to 1$$

$$1 \to (A^{\circ}_{g,\nu} \times | \rtimes \Pi_{g,\nu}) \to \widetilde{A}_{g,\nu} \to \Gamma_{g,\nu} \to 1$$

m384

Marginal note. m384 N.B. The second is meant to express that $\widetilde{A}^{\circ}_{g,\nu} = A^{\circ}_{g,\nu}$ and $\pi_0(\widetilde{A}_{g,\nu}) \simeq \Gamma'_{g,\nu+1}$ (the canonical extension of $\Gamma_{g,\nu}$ by $\Pi_{g,\nu}$).

[p. 127]

I would like to make $\widetilde{A}_{g,\nu}$ operate on $\widetilde{U}_{g,\nu}$, i.e. make d1 $H = \widetilde{A}^{\natural|\sharp}_{g,\nu}$ operate with operation d2 trivial on $A^{\circ}_{g,\nu+1}$, and this respecting the following conditions

m385

Marginal note. m385 trivial datum on $1 \times A^{\circ}_{g,\nu+1}$. Cf. generalization below in the margin.

a) d3 (compatibility with $\widetilde{A}_{g,\nu} \to A_{g,\nu}$) the pair $(u, v) \in H$ operates on $\widetilde{U}_{g,\nu}$ by an automorphism compatible with the automorphism u of i1 $U_{g,\nu}$ (we shall say that it is a u-automorphism).

b) (compatibility with $\Pi_{g,\nu} \to \widetilde{A}_{g,\nu}$) If $u = 1$, [so $v \in A^{\circ}_{g,\nu}$, so (since $v \in A^{\bullet}_{g,\nu}$) $v \in B_{g,\nu}$]i2 then the operation of $(u, v) = (1, v)$ on $\widetilde{U}_{g,\nu}$ is none other than that defined by $v \bmod B^{\circ}_{g,\nu} = A^{\circ}_{g,\nu+1}$, which is an element of $\Pi_{g,\nu} \simeq \mathrm{Aut}(\widetilde{U}_{g,\nu}/U_{g,\nu})$, or again, it is that defined by translation on the right$^{\text{i3}}$ by v^{-1}.

m386

Marginal note. m386 specification of the operation on $1 \times B_{g,\nu}$.

c) Compatibility with d4 the operation already d5 obtained above[i4] of $A^{\bullet}_{g,\nu}$ on $\widetilde{U}_{g,\nu}$: if $(u, v) \in H$ is such that $u = v$ (so $u = v \in A^{\bullet}_{g,\nu}$) then $(u, v) = (u, u)$ operates via the inner automorphism defined by u.

m387

Marginal note. m387 specification of the operation on $\delta(A^{\bullet}_{g,\nu})$ (δ: diagonal arrow).

d) Compatibility with $A^{\circ}_{g,\nu} \to \widetilde{A}_{g,\nu}$:[i5] The operation of $A^{\circ}_{g,\nu}$ on $\widetilde{U}_{g,\nu}$ is continuous (which, together with a), determines this operation uniquely d6 and[i6] the existence a priori of such an operation[i7] (follows from $\pi_1(A^{\circ}_{g,\nu}) = 0$)).

m388

Marginal note. m388 specification of the operation on $(A^{\circ}_{g,\nu}) \times 1$.

every element (u, v)[i8] of H can be written uniquely as a product of an element (v, v)[i9] of $\delta(A^{\bullet}_{g,\nu})$, with an element $(v^{-1}u, 1)$[i10] of $A^{\circ}_{g,\nu} \times 1$ (the first group normalizing the second)

m389

Marginal note. m389 N.B. The operation of $A^{\circ}_{g,\nu} \times 1$ is described most simply by translations of $A^{\circ}_{g,\nu}$ on the homogeneous space $\widetilde{U}_{g,\nu}$ of $A^{\circ}_{g,\nu}$.

[scan 254]

and an operation of this $\frac{1}{2}$ direct product is given indeed[i1] by [d1] specifying operations of the two factor groups, satisfying a compatibility condition, which is verified here by transport of structure. We have indeed defined an operation of $H = \widetilde{A}^{\natural\|\sharp}_{g,\nu}$ on the fibration (73), [d2] satisfying conditions c) and d) by the very construction, it remains to verify a) and b).

Now for a), it suffices to verify it separately for the elements of H in $\delta(A^{\bullet}_{g,\nu})$ and in $A^{\circ}_{g,\nu} \times 1$, where this is trivial by construction in both cases. It remains to verify b), i.e. to make explicit the operation of an element $(1, v)$, $v \in B_{g,\nu}$, which we write as

$$(\qquad (1, v) = (v, v)(v^{-1}, 1)$$

hence

$$\rho(1, v) = \rho(v, v)\rho(v^{-1}, 1).$$

Now $\rho(v, v)$ is induced by $\mathrm{int}(v)$, i.e. $x \mapsto vxv^{-1}$[i2] and $\rho(v^{-1}, 1)$ by left translation: $x \mapsto v^{-1}x$, so the composite operates by $x \mapsto xv^{-1}$. Phew!

[scan 255]

[p. 128]

We now assume that X_g is equipped with a C^∞ structure, and we replace in the considerations
d1 above the groups of homeomorphisms by groups of diffeomorphisms.
m390

Marginal note. m390 N.B. A $C^{\nu|r}$ structure with $\nu|r \geq 2$ would suffice

$$E_g = \text{set of conformal structures on } X_g \text{ compatible with its structure } C^\infty \tag{76}$$

d3 We see at once that E_g is an ∞-connected topological space, as a quotient of the ∞-connected space (a convex set)i2 of Riemannian structures, by the d4 ∞-connected group of C^∞ maps from X_g to $\mathbb{R}^{+*}$. On E_g the group A_g operates – but of course E_g is no longer a homogeneous space. Let us note at once

$$E_g/A_g \simeq \text{set of isomorphism classes of surfaces conformal compact orientable of genus } g \tag{77}$$

And if we choose one of the two orientations of X_g, so that E_g is identified with the set of complex structures on X_g compatible with its C^∞ structure and its orientationi4, then E_g/A_g is identified with the space of isomorphism classes of compact complex curves (nonsingular) connectedi5 of genus g, modulo passage to the complex conjugate. On the other hand

[p. 129]

$$\widetilde{M}_{g,\nu} = E_g/A^\circ_{g,\nu} \qquad (\widetilde{M}_g = \widetilde{M}_{g,0} = E_g/A^\circ_g) \tag{81}$$

on which the group [d1]

$$\Gamma_{g,\nu} = A_{g,\nu}/A^\circ_{g,\nu}$$

operates by passage to the quotient of the operation of $A_{g,\nu}$.

[d2] The space $\widetilde{M}_{g,\nu}$ (with the operation of $\Gamma_{g,\nu}$)[i1] is called the Teichmüller space of type g, ν. Of course we recover $M^{\natural|\sharp}_{g,\nu}$ from $\widetilde{M}_{g,\nu}$ and the operation of $\Gamma_{g,\nu}$ on it, by

$$M^{\natural|\sharp}_{g,\nu} = \widetilde{M}_{g,\nu}/\Gamma_{g,\nu} \tag{82}$$

Theorem (Teichmüller) The Teichmüller space $\widetilde{M}_{g,\nu}$ is homeomorphic to [d4] $\mathbb{C}^\mu$, where $\mu = 3g-3+\nu$ (in the[i2] anabelian cases $2g+\nu \geq 3$), and $\mu = 3g-3+(\nu+\delta)$

$$\delta = \dim_{\mathbb{C}} G$$

in the general case, G being group of algebraic automorphisms of a complex $U_{g,\nu}$ (so $\delta = 1$ in the "limiting" cases $(1,0)$ and $(0,2)$, and more generally[i3] δ increases by 1 each time for g fixed, and $(g, \nu-1)$ abelian, one passes from ν to $\nu-1$), hence

m393

Marginal note. [m393] We can also say that $\mu = 3g-3+\nu'$, where $\nu' = \nu$ in the anabelian case, and where ν' in the "general" case is the least integer $\geq \nu$ such that (g, ν') is "anabelian".

$$\begin{cases} \mu = 1 & \text{in the case } (1,0) \\ \mu = 0 & \text{in the cases } (0,2),(0,1),(0,0), \end{cases} \qquad (82_1|82')$$

i.e. $\widetilde{M}_{g,\nu}$ is in these cases reduced to a point, i.e. the action of $A^\circ_{g,\nu}$ on $E_g = E_0$ is [d1] transitive – (and these are with the anabelian case $(0,3)$[i1] the only three cases where this is so, [d2]).
m394

Marginal note. [m394] i.e. on surfaces oriented spherical with $\nu \leq 3$, all complex structures are isotopic.

Starting from $\widetilde{M}_{0,3}$, or from $\widetilde{M}_{1,1}$ or from $\widetilde{M}_{g,0} = \widetilde{M}_g$ with $g \geq 1$, when ν increases the "complex dimensions" of $\widetilde{M}_{g,\nu}$ increase by the same amount (On the other hand $\widetilde{M}_{1,0} \longleftarrow \widetilde{M}_{1,1}$ is a homeomorphism [d3]).

We can make Teichmüller's theorem more precise as follows

Corollary In the anabelian case, $A^\circ_{g,\nu}$ operates freely on E_g, so that E_g becomes a torsor over $\widetilde{M}_{g,\nu}$, with structure group $A^\circ_{g,\nu}$.

We deduce from this that $\widetilde{M}_{g,\nu}$ plays the role of a classifying space for $A^\circ_{g,\nu}$, and that

$$\pi_{i|\nu}(\widetilde{M}_{g,\nu}) \xrightarrow{\sim} \pi_{\nu-1|i-1}(A^\circ_{g,\nu}) \qquad (83)$$

and the fact that $\widetilde{M}_{g,\nu}$ is ∞-connected (contained in Teichmüller's theorem) is equivalent to

[p. 130]

the fact that $A^\circ_{g,\nu}$ is so – which is the "well-known theorem" recalled in number 19.

I do not dwell here on the interpretation of the points of $\widetilde{M}_{g,\nu}$ as isomorphism classes of complex curves, equipped [d1] with a[i1] suitable "Teichmüller rigidification", and the rigidified moduli spaces point of view, which makes it possible to verify a priori that $\widetilde{M}_{g,\nu}$ is equipped with the structure of a nonsingular complex manifold – but already the fact that $\widetilde{M}_{g,\nu}$ is simply

connected (which can express by interpreting $\widetilde{M}_{g,\nu}$ as the universal covering of the modular topos $M_{g,\nu}$) is quite deep, which does not seem to be able to fit into the framework of topology (or of differential topology (C^∞) alone...
m395

Marginal note. m395 N.B. To prove that the $\widetilde{M}_{g,\nu}$ are ∞-connected, we are easily reduced to the case of $M_{g,0}$ (if $g \geq 2$), or of $M_{1,1}$ (punctured elliptic case), by using the fibrations $A^\circ_{g,\nu}/A^\circ_{g,\nu+1} \simeq \widetilde{U}_{g,\nu}$ (which is ∞-connected...). The case $g = 1$ is moreover easy and well understood...

[scan 260]

Let us note that the subgroup inclusions

$$A^\circ_{g,\nu+1} \subset A^\circ_{g,\nu} \cdots \subset A^\circ_{g,0} = A^\circ_g$$

define a tower of continuous maps

$$\cdots \longrightarrow \widetilde{M}_{g,\nu+1} \longrightarrow \widetilde{M}_{g,\nu} \longrightarrow \cdots \longrightarrow \widetilde{M}_{g,0} = \widetilde{M}_g \tag{84}$$

where

$$\widetilde{M}_{g,\nu+1} \longrightarrow \widetilde{M}_{g,\nu} \tag{85}$$

is for (g,ν) anabelian[i1] a fibration with fiber $A^\circ_{g,\nu}/A^\circ_{g,\nu+1} \simeq \widetilde{U}_{g,\nu}$.

[it therefore has contractible fiber, and the ∞-connectedness of $\widetilde{M}_{g,\nu+1}$ is therefore equivalent to that of $\widetilde{M}_{g,\nu}$ – which brings us back to the case of $\widetilde{M}_g$ if $g \geq 2$, of $M_{1,1}$ and of $M_{0,3}$ if $g = | \neq | \geq 1$ or 0].

In the abelian case (g,ν), we find

$$\widetilde{M}_{g,\nu+1} \simeq \widetilde{M}_{g,\nu} \qquad \text{(if } (g,\nu) \text{ abelian)} \tag{85}$$

which [d2] means[i2] [d3] that in these cases, if we have two complex structures α, β[i3] on X which are congruent by $u \in$[i4] $A^\circ_{g,\nu}$, (i.e. $\beta = u.\alpha$)[i5] they are = congruent by $A^\circ_{g,\nu+1}$.

Indeed, if G is the identity|neutral component of the[i6] group of complex automorphisms of $U_{g,\nu}$ for β, we can write $u = gv$ with $g \in G$, $v \in A^\circ_{g,\nu+1}$ hence $\beta = gv.\alpha$ hence (since $g^{-1}\beta = \beta$) $\beta = v\alpha$, q.e.d.

Scans 261–270

[scan 261]

[p. 131] Thus $\widetilde{M}_{1,1} \simeq \widetilde{M}_{1,0}$ – and it is immediate that the latter is $\simeq$ the Poincaré half-plane. Likewise $\widetilde{M}_{3,0} \xrightarrow{\sim} \widetilde{M}_{2,0} \simeq \widetilde{M}_{1,0} \simeq \widetilde{M}_{00|0,0}$, and since A_0^0 is simply[i1] made up of the automorphisms of $X_0 \simeq S^2$ which preserve orientation, we see that two complex structures on S^2 are isotopic (since they are isomorphic, and an isomorphism preserves orientation i.e. is $\in A_0^0$) this proves that the $M_{0,i}$ $(i \leq 3)$ are reduced to a point|points ! Thus the Teichmüller Theorem is fairly evident if $g = 0$ or 1, it is the case $g \geq 2$ that is deep…

The Teichmüller space (more generally, any [d1] space E ∞-connected[i2] on which A_g operates in such a way that $A_{g,\nu}^0$ operates freely) will allow us to interpret the canonical extension $\Gamma'_{g,\nu+1}$ of $\Gamma_{g,\nu}$ by $\Pi_{g,\nu}$ (anabelian cases (g,ν)) as the mixed fundamental group of a [d2] space (homotopic to $U_{g,\nu}$) on which $\Gamma_{g,\nu}$ operates. (We were bothered previously, because $\Gamma_{g,\nu}$ did not itself operate on $U_{g,\nu}$, but only the group $A_{g,\nu}$ of which $\Gamma_{g,\nu}$ is a quotient, we had the impression

that passage to the quotient by $A_{g,\nu}^0$ was nevertheless inessential, since $A_{g,\nu}^0$ is ∞-connected – and moreover we had found an extension $\widetilde{A}_{g,\nu}$ of $\Gamma'_{g,\nu+1}$ by this same ∞-connected group $A_{g,\nu}^0$, which operates on the universal covering, [d1] [d2i1] with a homomorphism surjective[i2] $\widetilde{A}_{g,\nu} \to A_{g,\nu}$ with kernel $\simeq \Pi_{g,\nu}$ compatible with this operation…

Now if $\widetilde{M} = E/A^0_{g,\nu}$, E is an $A^0_{g,\nu}$-torsor with base $\widetilde{M}$, which we can use to twist [d3] $U_{g,\nu}$ on which $A^0_{g,\nu}$ operates continuously, we thus find a bundle $\mathcal{X}$ ($\simeq U_{g,\nu} \times E/A^0_{g,\nu}$ operating diagonally) over $\widetilde{M}$, with fiber $U_{g,\nu}$ (this is for $E = E_g$ the universal bundle of complex curves of type (g,ν) with Teichmüller rigidification…). Since E and $A^0_{g,\nu}$

[scan 268]

[p. 135] we know that the functor is 2-faithful, hence induces an equivalence of 2-categories

$$\mathcal{S} \longrightarrow \mathcal{M}_{\text{lac}}$$

m397

Marginal note. [m397] There is no [illeg. 3] [d1] [d2] in the case B_{D^*} = "empty topos" over B_U – namely an isomorphism $T \simeq H^2(U_i, Z)$ for every connected component [illeg. 1], – for we do not assume that we are working with Automorphisms|structures [illeg. 1] orientation ! (In the arithmetic analog, it is|it will be no longer the same, of course…)

If now Γ is a group, and if we consider admissible surfaces with an action of Γ, they define topoi (or groupoids)[i1] B_{D^*}, B_U with an operation of Γ on them [|(or topoi cofibered over the groupoid $[\Gamma]$ defined by Γ] and morphisms between them commuting with Γ. We can regard such a datum as that of a multi-Galois[i2] topos (or groupoid) cofibered over $\Delta \times [\Gamma]$. [d3] [d4] But the datum of such a morphism of multi-Galois topoi with an operation of Γ, is equivalent to that of a morphism of multi-Galois topoi[i3]

$$B_{D^*,\Gamma} \longrightarrow B_{U,\Gamma} \longrightarrow B_\Gamma$$

[scan 271]

equivalence of 2-categories,[i1] i.e. that it is 3 faithful.

Of course we are reduced all the same to the case of groupoids "connected"[i2] Π_f defined by a group (finite if need be)[i3], and we are also reduced by essentially trivial arguments to looking at the case of diagrams $B_{D^*} \to B_U$ with B_U connected.

On the geometric side, the situation would be given by a $U = X \setminus S$ of type (g, ν) $((g, \nu) \neq (0, 0))$, and an operation of Γ on it — we may suppose $U = U_{g,\nu}$, so we give $\Gamma \to A_{g,\nu}$. For the question of i-faithfulness with $i \leq 2$, we may suppose that it is the same group Γ that operates; [d1]

1) 0-faithfulness. [d2] Let U, U' be given with an operation of Γ on them, $f, g : U \xrightarrow{\sim} U'$ commuting with Γ, and α, β two homotopies from f to g[i4] i.e. two paths from f to g in $\underline{\mathrm{Isom}}_\Gamma(U, U')$, we suppose that in the topossic description|the topossic descriptions

$$\begin{array}{ccccc} B_{D^*,\Gamma} & \longrightarrow & B_{U,\Gamma} & \longrightarrow & B_\Gamma \\ {\scriptstyle f_{D^*,\Gamma}}\downarrow\downarrow{\scriptstyle g_{D^*,\Gamma}} & & {\scriptstyle f_{U,\Gamma}}\downarrow\downarrow{\scriptstyle g_{U,\Gamma}} & & \| \\ B_{D'^*,\Gamma} & \longrightarrow & B_{U',\Gamma} & \longrightarrow & B_\Gamma \end{array}$$

we have $\alpha_*^{D^*} = \beta_*^{D^*} : f_{D^*} \to g_{D^*}$ and $\alpha_*^U = \beta_*^U : f_U \to g_U$. To prove that α and β are homotopic. 270

[p. 137]

m400

Marginal note. m400 i.e. $f \in A_{g,\nu}$ commuting with the image of Γ under $\Gamma \to A_{g,\nu}$.

We may suppose $g = \mathrm{id}$, $U = U_{g,\nu}$, so $f \in A^{\Gamma}_{g,\nu}$, and we have two paths α, β from 1 to d1 f in the space $A^{\Gamma}_{g,\nu}$. We suppose that the two corresponding isomorphisms between the identity of Π_{D^*} i1 and $f_{D^*,\Gamma} : \Pi_{D^*_{S_\nu},\Gamma} \to \Pi_{D^*_{S_\nu},\Gamma}$ on the one hand, between the identity of $\Pi_{U,\Gamma}$ and $f_{U,\Gamma}$ on the other hand, are the same, we want to prove that α and β are homotopic. Of course, the hypothesis d3 on α, β concerning the action of Γ is satisfied a fortiori upon restricting to a smaller group, for example d4 $\Gamma' = 1$, and in fact we see that it is equivalent for Γ, and for its subgroup 1. d5 the already known result (Ladegallerie|Ladegaillerie) for $\Gamma = 1$, shows that this means that if two paths in A^{Γ} i2 from 1 to f are homotopic in A, they are so in A^{Γ} or again that

$$\boxed{\pi_1(A^{\Gamma}) \to \pi_1(A) \text{ is injective.}}$$

let us put $A = A_{g,\nu}$

In the case $\pi_1(A) = 0$ (case (g,ν) anabelian) this thus comes down to proving that $\pi_1(A^{\Gamma}) = 0$. 271

[p. 138]

Let A be a topological group, whence two invariants

$$\pi_0 = \pi_0(A), \qquad \pi_1 = \pi_1(A)$$

the first a group not necessarily commutative[i1], [d1] the second a commutative group on which π_0 operates. We define a Gr-category $\underline{A}$[i2] with invariants π_0, π_1 and corresponding to this operation of π_0 on π_1, by taking as underlying category the [d2] fundamental [d3] groupoid (naive) of A, and as composition functor the one deduced from $A \times A \to A$ (associativity in $\underline{A} = \Pi A$ is strict …)

This being so, every torsor under A defines a 1-torsor under the Gr-category $\underline{A}$. More generally, for $\forall$ topological space S (or $\forall$ topos which is locally a topological space) every torsor on S with group A_S defines an $\underline{A}_S$-[i3]stack on S which is a [d4] stack of A_S-torsors. If $\pi_i(A) = 0$ for $i \geq 2$, then we find 273

thus for $\forall n \in N,\ n \geq 2$[i1] an n-equivalence between the n-[i2]category of torsors on S with group A_S, and the n-category deduced from the 2-category of gerbes[i3] $\underline{A}_S$-torsors by extending it in a discrete way …

But let us consider [d1] a group Γ, and consider the classification of A_{B_Γ}-torsors on the classifying topos — i.e. that of A torsors, with an operation of Γ on them (commuting with the action of A). These objects form a 2-category, whose connected components correspond to the conjugacy classes of homomorphisms from Γ to A. If we have [d2] one[i4] homomorphism $\Gamma \to A$, it defines [d3] an action on the trivial torsor. 1_A If u, v are two homomorphisms, the isomorphisms from $(1_A, u)$ onto $(1_A, v)$ correspond to the elements of the set "

$$\mathrm{Transp}_A(u, v) = \{g \in A \mid v = \mathrm{int}(g).u\}$$

But we shall make a 0-isotopic category, 274

[p. 139]

by replacing $\mathrm{Transp}(u, v)$ by its π_0, and a 1-isotopic category by replacing it[i1] by its fundamental groupoid $\Pi_1 \mathrm{Transp}(u, v)$. Thus an isomorphism from u to v is still a point of $\mathrm{Transp}(u, v)$, but if we have two such isomorphisms f, g[i2], the isomorphisms $f \simeq g$ are the classes of paths in $\mathrm{Transp}(u, v)$ from f to g. Thus, the category $\underline{\mathrm{Aut}}(u)$ is equivalent to $\Pi_1 \underbrace{\mathrm{Trans}(u, u)}_{A^u}$ [d1]

$$\underline{\mathrm{Aut}}(u) \simeq \Pi_1 \mathrm{Trans}(u)$$

and the [d2] category $\mathrm{Isom}(u, v)$ is either empty (if u, v are not conjugate), or a torsor under $\underline{\mathrm{Aut}}(u)$.

But for every torsor P[i3] over A on which Γ operates, [d3]the[i4] [d4] 1-torsor [d5] $\Pi_1 P$ under $\Pi_1 A = \underline{A}$[i5] is equipped with operations of Γ, whence a 275

$(\Gamma, -\underline{A})$ torsor. We thus find a functor of 2-categories

$$\begin{array}{l}\text{2 category of}\\ \Gamma - A\text{-torsors}\\ \text{[or again, of homomorphisms } \Gamma \to A]\end{array} \longrightarrow \begin{array}{l}\text{2 category of 1-torsors under } A,\\ \text{with operations of } \Gamma \text{ on them.}\end{array}$$

In short, we have just repeated on the classifying topos B_Γ the construction made above[i1] for a topological space S. We would also like to express[i2] conditions for this [d2] 2-functor[i3] to be a 2-equivalence. For this, we should first have an understanding of the classification of the classes of equivalence|of equivalences of objects of the second category — which are, for their part, of a purely algebraic nature, in terms of the Gr-category $\underline{A}$ and of Γ. Even if we restrict ourselves to 276

[p. 140]

trivial torsors over $\underline{A}$ (which is legitimate) we would have to make explicit what it means that Γ operates on the trivial torsor. We observe that this means that we have a homomorphism of Gr-categories[i1] from the discrete Gr-category defined by[i2] Γ to $\underline{A}$. Thus the 2-category envisaged is the one whose objects are the homomorphisms of Gr-categories

$$\Gamma \xrightarrow{u} \underline{A}$$

and for two such morphisms u, v, we must define (not only a set $\mathrm{Hom}(u,v)$ but) a category $\underline{\mathrm{Hom}}(u,v)$, as the subcategory $\underline{\mathrm{Transp}}(u,v)$ of $\underline{A}$, to be defined ad-hoc.

Let us consider for simplicity the case where $\pi_1 = 0$, then $\underline{A}$ reduces to π_0, and the category of homomorphisms $\Gamma \to \underline{A}$ to that of homomorphisms $\Gamma \to \pi_0$. The 277

fact that the functor of 2-categories above [d1] is an equivalence of 2|1-categories then translates step by step as follows :

1°) 0 faithfulness means that for $\forall$ homomorphism $u : \Gamma \to A$, we have $\pi_1(A^u) = 0$

N.B. A^u and A^{0u} have the same identity component|identity components, so the condition is written : $\boxed{\pi_1((A^0)^u) = 0}$.[i1]

2°) 1-faithfulness means that moreover, if u, v are [d2] homomorphisms $\Gamma \rightrightarrows A$, and [d3] $\alpha, \beta \in \mathrm{Transp}_A(u,v)$ [d4] have the same image in $\mathrm{Transp}_{\pi_0}(\underline{u}, \underline{v})$[i2] [d5] [d6] then α, β are in the same [d7] connected component of $\mathrm{Transp}_A(u,v)$. [d8] [d9] [d10] To see this, we may suppose $u = v$, and we are reduced to expressing that the map $\pi_0(A^u) \to \pi_0$ is injective i.e. that [d11] its kernel is reduced to 1, i.e. that the open subgroup[i3] $(A^u) \cap A^0 = (A^0)^u$ of A^u is connected, i.e. 3°)

[p. 141]

3°) 2-faithfulness means that in addition to the preceding conditions, which ensure that for u, v fixed, the functor $\underline{\mathrm{Hom}}(u, v) \to \underline{\mathrm{Hom}}(\underline{u}, \underline{v})$ is fully faithful, that the latter is essentially surjective, i.e. that if u, v are such that $\underline{u}, \underline{v} : \Gamma \to \pi_0$ are conjugate, [d1] (equal if we wish) u, v are already conjugate (by an element[t] of $\underline{\pi_0}$)[i1]. In other words : for $\forall$ homomorphism $\underline{u} : \Gamma \to \pi_0 = A/A^0$, if there exists a lifting of u to $\Gamma \to A$, it is unique up to conjugation.

m411

Marginal note. [m411] We must say it [illeg. 1] in a stronger way : $\mathrm{Transp}(u, v) \to \mathrm{Transp}(\underline{u}, \underline{v})$ surjective — this is equivalent to saying that if $\underline{u} = \underline{v}$, then u and v are conjugate by an element of A^0.

4°) 3-faithfulness means that in addition, every homomorphism $\underline{u} : \Gamma \to \pi_0$ lifts to $u : \Gamma \to A$.

In summary, if $\pi_1(A^0) = 0$,[i2] 3-faithfulness means that for $\forall$ homomorphism $\underline{u} : \Gamma \to \pi_0 = A/A^0$, there exists [d2] lifting $u : \Gamma \to A$, unique up to conjugation, and that then $(A^0)^u$ is connected and simply connected, 279

[p. 142]

24 Attempt at[i1] Determination of|of the $\mathcal{A}^{0\Gamma}$. Link with the relation $\Pi^{\Gamma}_{g,(\nu,\nu+n-1)} = (1)$, and work program…

Let us consider an operation (faithful if we insist) of the finite group Γ on the surface $U \subset X = \widehat{U}$ of type (g, ν), $U = X - S$,[i2] let $\mathcal{A} = \mathrm{Aut}(U)$, so $\Gamma \subset \mathcal{A}$ and $\mathcal{A}^u = \mathcal{A}^{\Gamma}$ is the centralizer of Γ. Let us first assume $\Gamma = \Gamma^+$.[i3] Obviously $f \in \mathcal{A}^{\Gamma}$ implies that f [d1] induces an automorphism g of $X/\Gamma\equiv \mid \simeq X'$[i4] [d2] X is a Galois covering with group Γ.

Let S' be the image of S in X' (so $S = X \mid S'$), and let $S^!$ be the set of ramification points of Γ in U, $S'^!$ its image in $U' = X'\backslash S'$ (N.B. $U = X \mid U'$). Thus g is an automorphism of (X', S'), taking $S'^!$ into itself, and [d3] thus inducing an automorphism of $V' = U'\backslash S'^! = X' - (S' \cup S'^!)$, [d4] The inverse[i5] [d5] image[i6] $V = X \mid V'$ is étale over V', it is even a $\Gamma_{V'}$-torsor over V' and the inverse image of the latter under $g \mid V'$ is (via f) isomorphic to V. The datum of f is equivalent to the datum of an automorphism of the [d6] Γ-covering V of V', inducing an

[scan 283]

isomorphism of V' which, extended to X', sends S' into itself. This gives an interpretation of $\mathcal{A}^{\Gamma}$ in terms of constructions on X'.

Let us consider the fundamental group Π' of V', with the loop structure indexed by $S' \amalg S'^{!}$, so we have a surjective homomorphism

$$\Pi' \overset{\varphi}{\to} \Gamma$$

which on each[i1] of the subgroups with|of loops of index $s' \in S'^{!}$ is not trivial, and an automorphism g of V defines an outer automorphism $\mathfrak{g}|\overline{g}$[i2] of Π' – the condition to put on it is that its composite with φ is conjugate to|of φ, and that $\mathfrak{g}|\overline{g}$ takes $S'^{!}$ into itself.

m414

Marginal note. [m414] we choose a point $a \in V$ and its image $a' \in V'$ as base points, to make explicit [illeg. 1] $\pi|\Pi'$

This being so, [d1] g is defined by $\mathfrak{g}|\overline{g}$ up to isotopy [d2] (if we leave out degenerate cases (g', ν')[i3] [d3], namely $(0, \nu')$ with $\nu' = 0, 1, 2$ which will have to be examined separately…) and g being chosen, f is defined modulo multiplication by an element of the center of Γ, but we already know that $\mathcal{A}^0 \cap \Gamma = (1)$, so if we restrict ourselves to examining elements $f \in \mathcal{A}^{0\Gamma}$ then f will be uniquely determined by g

[scan 284]

[p. 143]

We are thus led to the following problem:

Let $V' = X' \setminus (S' \amalg S'^{!})$ be an [d1] admissible[i1] surface of type (g', ν') (X' compact, $\nu' = \operatorname{card} S' + \operatorname{card} S'^{!}$), equipped with a subset $S'^{!}$ of the set of its points at infinity and a base point x', whence $\Pi' = \Pi_1(X'|V', x')$. We are given a Galois covering connected|named V[i2] of V' with finite group Γ, pointed over x', hence defined by a surjective homomorphism

$$\Pi' \overset{\varphi}{\to} \Gamma$$

and we assume $V'|V$ ramified at each of the $s' \in S'^{!}$, i.e. (for a choice of the group with loops|group of loops [d2] $L_{s'}$ corresponding to s') that $L_{s'} \to \Gamma$ is not trivial. We consider the compactified set|space [d3] X of V, and the set S resp. $S^{!}$ of points of X over S' resp. $S'^{!}$. Let g be an automorphism of $V|V'$, defining an outer automorphism $g_\bullet$ of Π', we assume that

$$g^*(V'/V) \overset{V\text{-isomorphism}}{\simeq} V' \quad \text{i.e. that } \varphi \circ g_\bullet \text{ is conjugate to } \varphi$$

Marginal note. m415 We may assume that g fixes x', so $g_\bullet$ is a well-defined automorphism of Π'.

(|{which expresses that g comes by passage to the quotient from an automorphism f of V, defined modulo multiplication by an element of[i4] $z \in \mathrm{Center}\ \Gamma$). Let $U = V \cup S^! = X \setminus S$ (ramified covering over $U' = V' \cup S'^! = X' \setminus S'$), We want[i5] [d4] to express that [d5] among the f which lift[i6] g, there is one (necessarily|necessarily unique!) which is [d6] isotopic to 1 in $\underline{\mathrm{Aut}}(U)$ — i.e. which induces the trivial outer automorphism of $\Pi_1(U)$. We would like

[scan 285]

to prove that these are exactly those which [d1] are[i1] isotopic to 1 in $\underline{\mathrm{Aut}}(V')$ — or again that for such an f, f is necessarily isotopic to 1 in $\underline{\mathrm{Aut}}(V)$ [d2] i.e. is in $\underline{\mathrm{Aut}}(V)^0$ ($\subset \underline{\mathrm{Aut}}(V|U)^0$)[i2] and not merely in $\underline{\mathrm{Aut}}(U)^0$. Let us note when $\underline{\mathrm{Aut}}(V')^0$ is 1-connected[i3] that $\underline{\mathrm{Aut}}(V')^0$ lifts (by virtue of general principles) to [d3] [d4]

$$\underline{\mathrm{Aut}}(V')^0 \longrightarrow \underline{\mathrm{Aut}}(V)^{0\Gamma} \subset \underline{\mathrm{Aut}}(U)^{0\Gamma}.$$

Thus the stated condition on g of isotopy to 1 is certainly sufficient. Let us note moreover that the results already obtained imply that

$$\underline{\mathrm{Aut}}(U)^{\Gamma} \cap \underline{\mathrm{Aut}}(U)^{0} = \underline{\mathrm{Aut}}(U)^{0\Gamma}$$

induces the identity on $S^!$ (= $U^!$ with an earlier notation). Now [d6] let B [d7] $\subset \underline{\mathrm{Aut}}(U)^0 \cap \underline{\mathrm{Aut}}(U|V, S^!)_{=|\epsilon}$ [i4] be the subgroup of points which fix the $s \in S^!$, so that

$$\underline{\mathrm{Aut}}(U)^0/B \simeq \underline{\mathrm{Mon}}(S^!, U),$$

and $B^0 = \underline{\mathrm{Aut}}(V)^0$ — a known argument shows us that

$$B/B^0 \simeq \Pi_1(\underline{\mathrm{Mon}}(S^!, U)).$$

Since $\underline{\mathrm{Aut}}(U)^{0\Gamma} \subset B$ i.e. $\underline{\mathrm{Aut}}(U)^{0\Gamma} = B^{\Gamma}$, we [i5] [d8] [d9] :

$$\begin{array}{ccccccccc} 1 & \longrightarrow & B^{0\Gamma 0} & \longrightarrow & B^{\Gamma} & \longrightarrow & (B/B^0)^{\Gamma} & \longrightarrow & H^1(\Gamma, B^0) \\ & & \wr\downarrow & & \wr\downarrow & & & & \Vert ? \\ & & \underline{\mathrm{Aut}}(V)^0 & & \underline{\mathrm{Aut}}(U)^{0\Gamma} & & & & 1 \end{array}$$

[m416]

Marginal note. [m416] thus deduce from

$$1 \longrightarrow B^0 \longrightarrow B \longrightarrow B/B^0 \longrightarrow 1$$

previous one|previous one by an element of the kernel Π_1 of

$$\mathrm{Autext}_{\mathrm{lac|loc}}(\Pi', I'^{!}) \longrightarrow \mathrm{Autext}_{\mathrm{lac|loc}}(\Pi) \times \mathfrak{S}_{I'^{!}} \quad \ldots$$

We are going to restate the preceding conjecture in a slightly more general form. We are going to introduce a notation. If Γ is a finite group operating by outer automorphisms in an orientation-preserving way[i1] on a group with loops Π anabelian[i2], giving rise to an extension $\mathcal{E}|E$ of Π by Γ, we will denote by $\Phi = \Phi(\Pi, \Gamma)$ ("fixed points") the set of Π-conjugacy classes of maximal partial sections $\neq (1)$[i3] of the extension. (The intrinsic character of $\Phi(\Pi, \Gamma)$, independently of the particular choices of $\mathcal{E}|E$, has already been noted). It is clear that Φ is a Γ-set, we also know that it is finite.

Let now (Π', Γ) be an outer[i4] Γ-group with loops, with Γ operating in an orientation-preserving way ($\Gamma = \Gamma^{+}$) and faithfully (to simplify)[i5] let us fix a subset $I'^{!}$ of $I' = I(\Pi')$, stable under Γ, such that $\forall i' \in I'^{!}$, we have $\Gamma_{i'} \neq (1)$,[i6] and consider the quotient outer group, defined by plugging $I'^{!}$, namely Π [d1], – it is clear that Γ still operates on it. We want first to define a bijection

[p. 146]

$$(*) \qquad \Phi(\Pi, \Gamma) \xleftarrow{\sim} \Phi(\Pi', \Gamma)\Pi|\sqcup I'^{!}$$

m419

Marginal note. [m419] assuming Π, Γ also anabelian, to be more sure!

a) Map $I' \longrightarrow \Phi(\Pi, \Gamma)$

Let $L_{i'} \subset \Pi'$ be of class $i' \in I'$, $Z_{i'}$ its centralizer in the extension $\mathcal{E}|E'$ of Γ by Π' so that $L_{i'}$ is an extension of $\Gamma_{i'}$ by $L_{i'}$. The passage to the quotient $\mathcal{E}|E' \longrightarrow \mathcal{E}|E$ defines a partial section $\Gamma_{i'} \hookrightarrow \mathcal{E}|E$, contained in a unique maximal partial section (probably it is already maximal =|itself?…)[i1]. [m420]

Marginal note. m420 Yes, because for [illeg. 2] Γ cyclic, [illeg. 5] realizable…! ?

We thus find a map $I' \longrightarrow \Phi(\Pi, \Gamma)$, obviously compatible with the actions of Γ.

b) Map $\Phi(\Pi', \Gamma) \longrightarrow \Phi(\Pi, \Gamma)$

Every partial section $\neq 1$ i2 of $\mathcal{E}|E'$ over Γ obviously defines one of $\mathcal{E}|E$ over Γ by passing to the quotient, we know as above that a maximal section gives a maximal section, by reducing to the case Γ cyclic. m421

Marginal note. m421 not clear, since the hypothesis that the $\Gamma_{i'} \neq (1)$ risks|risk not being satisfied|satisfied

c) Bijectivity of (*). d1 It is not i3 d2 proved (except if the initial situation is i4 realizable, or if $I'^!$ reduced to a single element …but then Γ cyclic and the situation is realizable…)

[scan 291]

This d1 granted i1 we have defined i2 a functor

$$(\pi', \Gamma, I'^!) \longmapsto (\pi, \Gamma, I'^!)$$

going from the category of outer Γ-groups with loops π' i3 equipped with a subset $I'^!$ of $I' = I(\pi')$ stable d2 such that $s' \in I' \Rightarrow \Gamma_{s'} \neq (1)$, i4 under Γ, to the category of outer Γ-groups with loops, equipped with a subset $I'^!$ of $\Phi(\pi, \Gamma)$. The conjecture is that the functor (itself somewhat conjectural, unless we restrict to realizable source situations, whence target situations also realizable) is an equivalence of categories, i.e. 1°) fully faithful and 2°) essentially surjective. d3

The point 2°) is clear, when we restrict on both sides to realizable situations. But even in this case, the point 1°) is not proved. d4 I think i5 that d5 if I' is reduced to one element, then the i6 d6 properties of the "drilling a hole" functor will allow us to establish it easily. We also see that to establish it, we are

[p. 147]

reduced to establishing the bijectivity of the $(*)$, and the theorem of equivalence in the case where Γ is transitive on $I'^{!}$.

To summarize, the Program of attack on the Problem of realizability of an outer Γ-group with loops would be the following

I) Establish the bijectivity of the $(*)$ in the general case

(II) Establish the full faithfulness of the preceding functor (by reducing if necessary to the case where $I'^{!}$ is one orbit (singular) of Γ in $I' = I(\pi')$.

(III) In the case where $\Phi(\pi, \Gamma) = \emptyset$ i.e. the extension $\mathcal{E}$ has no element of finite order $\neq 1$, prove that $\mathcal{E}$, equipped with the set[i1] of $\mathcal{E}$-conjugacy classes of the centralizers of the L_i $(i \in I(\pi))$ in $\mathcal{E}$, is a group with loops.

Moreover, to have the indispensable preliminary properties of the sets $\Phi(\pi, \Gamma)$, we would have to begin by carrying out this program for the

cyclic groups (operating in a direct way), and proceed in this case by dévissage.

If the complete classification theorem (as an equivalence of the 2-categories –of operations[i1] that are topological and of isotopic|homological operations –) were true, points I, II, III of this program should be so too, and it would therefore be a good program of approach. Points I and II should be valid, as soon as the 2-functor between 2-categories were 2-faithful (not necessarily [d1] 3-faithful), [d2] at least for[i2] realizable situations. We would thus say that an outer[i3] action of Γ on a π', equipped with an $I'^{!}$, is admissible, if [d3]

$$\operatorname{Aut}\operatorname{ext}(\pi', \Gamma, I'^{!}) \xrightarrow{\sim} \operatorname{Aut}(\pi, \Gamma, I'^{!})$$

and if moreover every [d4] other action of Γ on π', [d5] the same action on π and the same map $I'^{!} \longrightarrow |-\Phi(\pi, \Gamma)$, is conjugate to the original action

[p. 148]

This posited, the necessary and sufficient condition for realizability of an outer faithful[i1] action of Γ on a π would then be that this action lifts (by "drilling holes" [d1] for $I'^{!} = \Phi(\pi, \Gamma)$[i3])[i2] to an action admissible,[i4] of Γ on a $(\pi', I'^{!})$, [d2] (by the very definition, this lifting would be [d3]

then essentially unique) and that moreover the corresponding extension $\mathcal{E}'$ of Γ by π' be a group with loops.

25. Special Teichmüller groups.

Let us return to the notation of number 19, We are going to define a subgroup $SA_{g,\nu}^{\dagger|!}$ of $A_{g,\nu}^{!}$

$$SA_{g,\nu}^{\dagger|!}\{ = \{u \in A_g \mid u \text{ induces the identity on a neighborhood of } S_{g,\nu}\}$$

(set of automorphisms of $U_{g,\nu}$ which)[i5] i.e. [d6] induce|induces the identity in|in the complement of a compact set.

Unlike the other subgroups of A_g considered so far, this one is not a closed subgroup. N.B. In the case where we work on compact surfaces

[scan 296]

[p. 149]

the group of outer automorphisms of the group with loops $\pi_{g,\nu}$, inducing the identity on $S_{g,\nu} = I(\pi_{g,\nu})$.

d1 d2 For $i \in I = S_{g,\nu}$, let us choose an d3 L_i of class i in $\pi_{g,\nu}$ — which amounts to giving oneself a "point" of the|of $B_{D^*_i}$ ($\simeq$ a universal covering $\widetilde{D}^*_i$)[i1] d4 and an isomorphism between its image in $B_{U=U_{g,\nu}}$ with the d5 reference "point" $s = s_{g,\nu}$, which served to define $\pi_{g,\nu}$ as $\mathrm{Aut}_{B_U}(s) \simeq \pi_1(B_U, s)$.

This said, if u is an automorphism of $\pi = \pi_{g,\nu}$, the fact that it respects (strictly, by inducing the identity on $S_{g,\nu}$)[i2] the loop structure*, is expressed by the existence of a family of elements $g_i \in \pi$, such that

$$u(\ell) = \mathrm{int}\, g_i^{-1}(\ell^\alpha) \qquad (i \in I, \forall \ell \in L_i)$$

— which|which g_i are determined by u d9 modulo right multiplication by a $\lambda_i \in L_i$. If we likewise have $v, (h_i)$, then d10 For $\ell \in L_i$ we have

where $\alpha = \chi(u)$

$$\begin{aligned}(vu)(\ell) = v(\underbrace{u(\ell)}_{\mathrm{int}(g_i^{-1})\ell^\alpha}) &= v(\mathrm{int}(g_i^{-1}))v(\ell)^\alpha \\ &= \mathrm{int}(v(g_i^{-1}))\,\mathrm{int}(h_i^{-1}) \cdot (\ell^{\alpha\beta}) \\ &= \mathrm{int}(v(g_i^{-1}) \cdot h_i^{-1}) \cdot \ell^{\alpha\beta} = \mathrm{int}((h_i \cdot v(g_i))^{-1})\ell^{\alpha\beta}\end{aligned}$$

thus vu is compatible with the system of d11 $h_i v(g_i)$ Let us put

N.B. $\alpha = \chi(u)$ $\beta = \chi(v)$

[p. 151]

In fact, in all this there was no reason at all to restrict ourselves to the [d1] automorphisms[i1] of π (outer or total) inducing the identity on I. In any case we find extensions $S\mathcal{E}|\varepsilon$ of $\mathcal{E}|\varepsilon$ by $T|\mathbb{T}^I$, $S\Gamma$ of Γ by $T|\mathbb{T}^I$, and a homomorphism of extensions

so that we can consider $S\mathcal{E}|\varepsilon$ as an extension of Γ by $T|\mathbb{T}^I \times \pi$

$$1 \longrightarrow T|\mathbb{T}^I \times \pi \longrightarrow S\mathcal{E}|\varepsilon \longrightarrow \Gamma \longrightarrow 1$$

from which the extension[i2] $\mathcal{E}|\varepsilon$ resp. $S\Gamma$ is obtained by dividing by $T|\mathbb{T}^{I|S}$ resp. by π.

†[d2]|Returning now to the model case [d3] $U_{g,\nu} = X_{g,\nu} \setminus S_{g,\nu}$, we will use|use the|some notations

$$\mathcal{E}|\varepsilon_{g,\nu} = \mathrm{Aut}_{\mathrm{lac}}(\pi|\Pi_{g,\nu})$$

($\overset{\mathrm{can}}{\simeq} \Gamma_{g,\nu+1}$ if $(g,\nu) \neq (0,0),(0,1)$ i.e. [d6]) [illeg. 1]

and

$$S\Gamma_{g,\nu} = S\mathrm{Autext}_{\mathrm{lac}}(\pi|\Pi_{g,\nu})$$

(extension of $\Gamma_{g,\nu}$ by $T|\mathbb{T}^I$)

and $S\mathcal{E}|\varepsilon_{g,\nu}$ ($\simeq S\Gamma'_{g,\nu+1}/T|\mathbb{T}|\Gamma_{s_\nu|g,\nu}$ [d7] where $S\Gamma'_{g,\nu+1}$ denotes the[i3] subgroup of $S\Gamma'_{g,\nu+1}$ of the elements which fix the last element s_ν …)

Scans 301–310

[scan 301]

We denote by $S\Gamma^!_{g,\nu}$ and $S\mathcal{E}|\varepsilon^!_{g,\nu}$ the subgroups|subgroups of the preceding $S\Gamma_{g,\nu}$, $S\mathcal{E}|\varepsilon_{g,\nu}$ which induce the identity on $I = S_{g,\nu}$.

And let us finally return to the relations with $SA|\mathcal{A}_{g,\nu}$, we are going to define

$$SA_{g,\nu} \longrightarrow S\Gamma^{!+}_{g,\nu}$$

by [d1] noting that if a $u \in A_{g,\nu}$ induces the identity in a neighborhood of $S_{g,\nu}$, then $u_\bullet|u_i(\widetilde{D}_i^*|\widetilde{D}_i)\simeq | = \widetilde{D}_i^*$ and we shall be able to define an element of $S\Gamma^!_{g,\nu}$ by taking as γ_i the

identities. The fact that the homomorphism obtained is trivial on $(SA_{g,\nu})^0$ is probably trivial, hence

$$SA_{g,\nu}/(SA_{g,\nu})^0 \longrightarrow S\Gamma^{!+}_{g,\nu}.$$

To say that this is surjective means that $\forall$ automorphism $\in A^{!+}_{g,\nu}$ (i.e. all|the automorphisms of $U_{g,\nu}$ inducing the identity on $S_{g,\nu}$ and respecting the orientation)[i1] is isotopic (by an isotopy, if one wishes, which remains the identity outside a small neighborhood of $S_{g,\nu}$) to an automorphism which is the identity on a neighborhood, this is easy. Injectivity perhaps more delicate, it comes down essen

must be interpretable as an exact sequence

$$\begin{cases} 0 \longrightarrow \Pi_1|\pi_1((SA|\mathcal{A}_{g,\nu})^0) \longrightarrow \Pi_1|\pi_1(A^0_{g,\nu}) \longrightarrow T^I \longrightarrow \Pi_0|\pi_0(SA^{!+}_{g,\nu}) \longrightarrow \Gamma^{!+}_{g,\nu} \longrightarrow 1 \\ \Pi_i|\pi_i((SA_{g,\nu})^0) \xrightarrow{\sim} \Pi_i|\pi_i(A^0_{g,\nu}) \quad \text{for } i \geq 2. \end{cases}$$

In the anabelian case, we do indeed find, since $\Pi_1|\pi_1(A^0_{g,\nu}) = 0$, an extension structure

$$\boxed{1 \longrightarrow T^{S_{g,\nu}} \longrightarrow \Pi_0|\pi_0(SA_{g,\nu}) \longrightarrow \Gamma^{!+}_{g,\nu} \longrightarrow 1}$$

d1 and moreover

$$\Pi_i|\pi_i((SA_{g,\nu})^0) = 0 \quad \text{for } i \geq 2.$$

In the abelian case, we must make explicit [d2]

$$\Pi_1|\pi_1(A^0_{g,\nu}) \longrightarrow T^{S_{g,\nu}}$$

and we are going to distinguish the [d3]two[i1] abelian cases (with the understanding that we have $I \neq \emptyset$!) — we have|i.e. always $g = 0$, $\nu = 1$ or 2. [d4i2]

In any case, introducing a complex|complex analytic structure and the group G, identity component of the group of complex automorphisms, we have have

$$G \overset{\approx|\sim}{\longrightarrow} A^0_{g,\nu}.$$

[d5] :

a) Case $g = 0$, $\nu = 2$ [d6] $G \simeq \mathbb{C}^*$, [d7] we see that if the loop structure of $\pi|\Pi$[i3] is defined by the two isomorphisms $k_i|\kappa_i : T \longrightarrow \pi|\Pi$ ($i \in I = \{s_{g0}|s_{0,0}|s_\infty, s_{0g}|s_{0,1}|s_0\}$)

We are going to make explicit a compatibility relation for $S\Gamma$ relative to a π with loops, fixing an $i \in I = \mathcal{I}(\pi)$, hence a stabilizer $\Gamma_i \subset \Gamma$ whose inverse image $(S\Gamma)_i$ in $S\Gamma$ is thus an extension

of Γ_i by T^I. Using the projection $T^I \xrightarrow{\mathrm{pr}_i} T$, we find an extension of Γ_i by T, which we are going to describe in another way. The extension $S\Gamma$ is defined intrinsically by the datum of I realizations $(\pi_i)_{i\in I}$[i1] of the group outer π by groups, with in each π_i an $L_i \subset \pi_i$ of class i (that is it, the datum of a system of the $(\widetilde{D}_i^*)$!). For an outer automorphism [d1] with loops $u \in \Gamma$[i2] of π, [d2] for $\forall i$ it [d3] is possible[i3] to realize it by $u_i \in \mathrm{Aut}_{\mathrm{lac|loc}}(\pi_i)$, with $u_i(L_i) \subset L_i$ — this u_i is determined modulo right multiplication by an $\mathrm{int}(k_i|\kappa_i(\alpha))$, where $\alpha \in T$. Of course, $S\Gamma$ is the subgroup of the|of the [p. 304]

[scan 306]

[p. 154] $\prod_{i\in I} \mathrm{Aut}_{\mathrm{lac|loc}}(\pi_i)$, [d1] the inverse image[i1] of the diagonal under the natural homomorphism from this product to $\mathrm{Autext}_{\mathrm{lac|loc}}(\pi)^I$, [d2] which is indeed[i2] extension of the said diagonal (identified with Γ) by T^I. If we look at the subextension [d3] obtained by restriction to Γ_i, we see that the projection $T^I \xrightarrow{\mathrm{pr}_i} T$ is stable under Γ_i; thus we deduce from it an extension of Γ_i by T, which is none other than the group of automorphisms with loops[i3] of π_i which normalize L_i — which is indeed an extension of Γ_i by L_i (for intersection with $\pi_i \subset \mathrm{Aut}_{\mathrm{lac|loc}}(\pi_i)$ is|being reduced to L_i).

This shows us that the extension of Γ by T^I has a marked tendency not to be trivial, for this is so (for $i \in I$ fixed)[i4] for the extension of Γ_i by T to[i5] which it gives rise. If for example we have a finite subgroup $G \subset \Gamma_i^+$, the induced extension is never trivial if $G \neq 1$, we have seen this. In fact, G must be cyclic and its inverse image in the extension in question is $\simeq T$…[p. 305]

[scan 307]

[p. 155] 25bis. Case of the two groups. Return to the notations

We place ourselves first[i1] to fix ideas in the topological and discrete case, but the motivation is the case of an algebraic curve U over a finitely generated field K, where we have both the group $G_K = \mathrm{Aut}_K(U)$ and $\Gamma = \mathrm{Gal}(\overline{K}/K)$ which operate by outer automorphisms on $\pi_1(U_{\overline{K}})$. In this case, G and Γ commute, but we can look more generally at the case of the group (bigger than G_K) $G_{\overline{K}} = \mathrm{Aut}_{\overline{K}}(U)$, on which Γ operates (in a not necessarily trivial way — this operation describes a finite étale algebraic group over K.

Anabelian case so $G|G_K$ finite

So suppose we have a surface U (orientable, $U = X - S$, X compact connected[i2], S finite) on which|which operate two groups G, Γ, the action of Γ normalizing that of G — so we have a group $\mathcal{G} = \Gamma.G$ (semidirect product, for a certain action of Γ on G) which operates on U. We suppose G finite, but not necessarily Γ finite. [p. 306]

[scan 308]

We suppose chosen a universal covering $\widetilde{U}$ of U, hence a group with loops $\pi = \mathrm{Aut}(\widetilde{U})$, on which $\mathcal{G}$ operates by outer automorphisms, hence extension

$$(1) \qquad 1 \longrightarrow \pi \longrightarrow \mathcal{E}|\varepsilon \longrightarrow \mathcal{G} \longrightarrow 1$$

m429

Marginal note. [m429] We are going to suppose the action of $\mathcal{G}$ faithful

If the action of $\mathcal{G}$ on U modulo isotopy[i1] is faithful, then $\mathcal{G} \hookrightarrow \mathrm{Autext}(\pi)$, and the preceding extension is the inverse image of the Teichmüller extension of π

$$1 \longrightarrow \pi \longrightarrow \mathrm{Aut}_{\mathrm{lac}}(\pi) \longrightarrow \mathrm{Autext}_{\mathrm{lac}}(\pi) \longrightarrow 1.$$

[d1] We shall have to look at other universal covering[s] than $\widetilde{U}$, and their isomorphisms with $\widetilde{U}$. When $\widetilde{U} = \widetilde{U}(P)$ is the universal covering based at a certain $P \in U$, then for universal coverings $U(Q)$[i2] based at [d2] a[i3] point†[d3]|points, the U-[i4]isomorphisms $\widetilde{U}(P) \xrightarrow{\sim} \overline{U}(Q)|\widetilde{U}(Q)$ correspond thus to the classes of paths from P to Q.

Let [d4] $Q \in U$ be such that its isotropy group G_Q[i5] [d5] in G is such that $G_Q^+ \neq 1$. (So G_Q^+ is cyclic). Choosing a [p. 307]

[p. 156]

class of paths λ[i1] from P to Q, identifying $\overline{U}(P)|\widetilde{U}(P)$ with $\overline{U}(Q)|\widetilde{U}(Q)$, we find an operation of G_Q on $\widetilde{U}(P)$ i.e. a lifting $G_Q \xrightarrow{r_{G_Q}} \mathcal{E}|\varepsilon$ in the extension (1) — the change of class of paths from λ to λ'[i2] will give a lifting r'_{G_Q} which [d1] will be conjugate to r by a unique element of $\pi = \pi_1(U, P)$[i3] (uniqueness comes from $\pi^{G_Q} = \{1\}$), namely the one which makes one pass from one path to another.

Let us consider the stabilizer Γ_Q of Q in Γ, [d2] which of course operates on $\widetilde{U}(Q)$ just like G_Q (in fact it is $\mathcal{G}_Q$ which operates hence $r : \mathcal{G}_Q \to \mathcal{E}|\varepsilon$[i4] …), so via λ we also have a lift[ing]|lifting $r_{\Gamma_Q} : \Gamma_Q \longrightarrow \mathcal{E}|\varepsilon$, which has[i5] even the property of normalizing r_{G_Q} (i.e. operation of [d3] Γ_Q on it, which is the one coming from the given operation of Γ on G). [m430]

Marginal note. [m430] N.B. As the set [d4] of points Q is finite, and $\mathcal{G}$ operates on it, the orbit of Q under $\mathcal{G}$ is finite, i.e. $\mathcal{G}_Q$ of finite index in $\mathcal{G}$. and likewise Γ_Q in Γ.

To simplify, let us suppose all the same that Γ operates trivial[ly] on G i.e. $\mathcal{G} = \Gamma \times G$, then $r_{\Gamma_Q}(\Gamma_Q) \subset \mathcal{E}|\varepsilon$ is contained in the centralizer of r (or of[i6] $r_{G_Q}(G_Q)$), [p. 308]

Scans 311–320

[scan 311]

[p. 157]

The set $\widetilde{U}|U^{!}$ of points $Q \in U$ such that $G_Q^+ \neq (1)$ is stable under the action of $\mathcal{G}$, and is identified (with this action) with the set of maximal[i1] liftings modulo π of (cyclic) subgroups $\neq 1$ of G^+. When one knows, for a partial lifting r of a G_Q into $\mathcal{E}$ what its centralizer in $\mathcal{E}$ is i.e. the corresponding lifting of $\mathcal{G}_Q$, well|then in the $=$ way for the conjugates of r by any element g (not only of π, but $=$ of $\mathcal{E}$), by simple conjugation.

So the cases to be determined correspond in practice to the orbits of $\mathcal{G}$ in $U^!$.

One may be interested in describing $\mathcal{G}$ or Γ as a subgroup of $\operatorname{Aut}\operatorname{ext}_{\text{lac}}(\pi) = \Gamma'$ giving rise to the extension $\mathcal{E}'$ of Γ' by π (thus $\mathcal{E} \subset \mathcal{E}'$).[i2] But for every lifting r of a G_Q, let us consider $\operatorname{Centr}_{\mathcal{E}'}(r)$, [d2] . we shall have|we still have $\operatorname{Centr}_{\mathcal{E}'}(r) \cap \pi = (1)$ i.e. we find a section over[i3] the image of this centralizer in Γ', say $\Gamma'(Q)$. This image depends only on Q i.e. on the π-conjugacy class of r or of $r(G_Q)$, and is replaced by a G-conjugate when Q is replaced by a G-conjugate. This

said, the intersection $\Gamma'^{\natural}$[i1] of the $\Gamma'(Q)$, for $Q \in U^!$, is a subgroup of Γ' which contains the intersection [d1] $\mathcal{G}^{\natural}$ of the $\mathcal{G}_Q$, and the centralizer of G in $\Gamma'^{\natural}$ contains in the $=$ way the intersection [d3] $\Gamma^{\natural}$ of the Γ_Q, which is an invariant[i2] subgroup of finite index in Γ. And one can then propose to oneself whether it is possible to characterize at least the|a finite subgroup $\Gamma^{\natural}$ of Γ as $\operatorname{Centr}_{\Gamma'^{\natural}}(G)$, and to recover from it perhaps Γ as the normalizer of $\Gamma^{\natural}$ in [d4] $\operatorname{Centr}_G(\Gamma)$.

I am more particularly interested in the profinite variant of this, in the case where $U = \mathbb{P}^1_{\mathbb{Q}} \setminus \{0, 1, \infty\}$, $G = \mathfrak{S}_3$, $\Gamma =$ Galois group of $\overline{\mathbb{Q}}/\mathbb{Q}$, [d5] $P|\rho = \exp(2i\pi/6)$[i3].

algebraic closure in $\mathbb{C}$

I have not checked that $\Gamma \longrightarrow \mathrm{Autext}_{\mathrm{lac}}(\hat{\pi})$ is injective, this does not prevent doing calculations in $\mathrm{Aut}_{\mathrm{lac}}(\hat{\pi})$, be they heuristic for the moment.

[p. 158]

I am running into notational troubles – too many groups are denoted by the letter Γ (possibly with primes, subscripts, superscripts …). There are three types of groups that enter into my reflections:

a) the Teichmüller groups and its variants, which play the role of the|of "universal" groups operating (possibly[i1] modulo isotopy) on surfaces, or on outer groups [d1] with loops. These groups tend to be infinite

b) Groups (most often finite) operating on topological surfaces, or on geometric algebraic curves (without, in that case, moving the base field).

m433

Marginal note. [m433] Cases b) and c) sometimes mix (in a G groups $\mathcal{G}$ extension of a Galois group Γ by a finite group G) in the case of G Algebraic Geometry.

c) Profinite Galois groups (hence infinite), chiefly of fields of finite type over $\mathbb{Q}$, operating "arithmetically" on surfaces and their geometric $\hat{\pi}_1$.

It is because of the deep analogies between cases b) and c), and their close relations with case a), that I had been led to adopt common notations, but

[p. 312]

[scan 314]

which in the long run end up leading to collisions. There is thus reason to review the notations. I will reserve the letter G and variants[i1] for geometric actions (case b)) of groups, most often finite, the letter Γ and variants[i2] for Galois groups, the letter $\mathcal{G}$ for mixed groups.

As for the "universal" groups of Teichmüller type, like those denoted $\Gamma_{g,\nu}$ previously, I will instead denote them $\mathcal{T}$,[i3] $\mathcal{T}_{g,\nu}$ (initial of "Teichmüller", whereas Γ, G[i4] are the initial of Galois).

The Galois group over $\mathbb{Q}$[i5] of the algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$ in $\mathbb{C}$ [d1] deserves a special letter, I will denote it $\mathbf{\Gamma}$. The quotient [d2] $\mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}_{g,\nu}}(\widehat{\mathcal{T}}_{g,\nu})/\widehat{\mathcal{T}}_{g,\nu}$, which is more akin to a Galois group than to a Teichmüller group, will be denoted $\mathbf{\Gamma}_{g,\nu}$ (bold letter!). In the

[p. 159]

case $(g,\nu) = (0,3)$ which occupies me more particularly, $\mathbf{\Gamma}_{0,3}$ is identified with the [d1] centralizer[i1] of $G = \mathfrak{S}_3 = \mathcal{T}^+_{0,3}$[i2] in $\widehat{\widehat{\mathcal{T}}}_{0,3}$ – it is contained in $\widehat{\widehat{\mathcal{T}}}^{!}_{03}$, and perhaps equal.[i3] We have a canonical homomorphism [m434]

Marginal note. [m434] $\widehat{\widehat{\mathcal{T}}}$ is here the $\frac{1}{2}$ direct product of $\mathfrak{S}_3 = \mathcal{T}^+$ by $\mathcal{T}^!$

$$\mathbf{\Gamma} \longrightarrow \mathbf{\Gamma}_{03} \qquad \text{(more generally } \mathbf{\Gamma} \longrightarrow \mathbf{\Gamma}_{g,\nu}\text{)}$$

for which I do not know for the moment whether it is injective, and still less whether it is surjective. The preceding reflections suggest conditions on the image, which are especially interesting if one admits the relations

$$\hat{\pi}^{\rho} = \hat{\pi}^{\sigma_0} = (1)$$

We have[i4] denoted†[d2] by $\mathcal{E}_{g\nu}$ the canonical extension of $\mathcal{T}_{g,\nu}$ by $\pi_{g,\nu}$ (which for (g,ν) anabelian is identified with $\mathcal{T}'_{g,\nu+1}$).

The outer operation of a group G, Γ or $\mathcal{G}$ also defines an extension by π (or by $\hat{\pi}$), which we have also denoted|denoted by the letter $\mathcal{E}$ (initial of extension) – there is again a collision of notations.

[scan 319]

m437

Marginal note. [m437] or again, one defines $\Pi_{g,\nu}$ as the discrete group with|with the generators the x_i, y_i, ℓ_j and with defining relation (4)

If one chooses in $\Pi_{g,\nu}$ a (discrete) basis (corresponding definition|Definition), whence a basis of $\widehat{\Pi}_{g,\nu}$, one will have an obvious bijection

$$\mathrm{Bases}(\pi) \overset{\sim}{\leftarrow} \mathrm{Isom}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu}, \pi) \tag{5}$$

The set of bases of π is a homogeneous set in|under [d1] $\widehat{\widehat{\mathfrak{S}}}(\pi) = \mathrm{Aut}_{\mathrm{lac}}(\pi)$. Let|If the [d2] basis corresponds to an isomorphism $u : \widehat{\Pi}_{g,\nu} \longrightarrow \pi$, the group Π_0[i1] generated by the x_i, y_i, ℓ_j is none other than $u(\Pi_{g,\nu})$. [d4] the subgroups[i3] of π which can be obtained in this way are called the discretifications of π. These form a homogeneous set under $\widehat{\widehat{\mathfrak{S}}} = \mathrm{Aut}_{\mathrm{lac}}(\pi)$, canonically[i4] isomorphic to the quotient of the right $\widehat{\widehat{\mathfrak{S}}}_{g,\nu}$-[d5]set[i5] $\mathrm{Isom}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu}, \pi)$ by $\mathfrak{S}_{g,\nu}$:

$$\mathrm{Discrt}(\pi) \overset{\sim}{\leftarrow} \mathrm{Isom}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu}, \pi)/\mathfrak{S}_{g,\nu} \tag{6}$$

The automorphisms (profinite with loops)[i6] of π fixing a discretification[i7] Π_0 are identified with the automorphisms of the discrete group with loops[i8] Π_0.

$$\mathrm{Aut}_{\mathrm{lac}}(\pi, \Pi_0) \simeq \mathrm{Aut}_{\mathrm{lac}}(\Pi_0) \tag{7}$$

[p. 162]

The bijection (5) puts on the set of Bases of π a bitorsor structure under $\widehat{\widehat{\mathfrak{S}}}(\pi), \widehat{\widehat{\mathfrak{S}}}_{g,\nu}$, and the|the corresponding|corresponding topologies|topology makes it a profinite set. The set of discretifications of π, which is a quotient of the preceding set, inherits a quotient topology, which is none other than the quotient topology of the right-hand side of (6). [d1] This space is[i1] not Hausdorff (N.B. $\mathfrak{S}_{g,\nu}$ is always infinite)[i2], for the group $\mathfrak{S}_{g,\nu} \subset \widehat{\widehat{\mathfrak{S}}}_{g,\nu}$ is not closed. We denote by $\widetilde{\text{Discrt}}' \,|\, \text{Discrt}'(\pi)$ the associated Hausdorff topological space, identified with $\text{Isom}_{\text{lac}}(\widehat{\Pi}_{g,\nu}, \pi)/\overline{\mathfrak{S}}_{g,\nu}$, where $\overline{\mathfrak{S}}_{g,\nu}$ denotes the closure of $\mathfrak{S}_{g,\nu}$ in $\widehat{\widehat{\mathfrak{S}}}_{g,\nu}$. We moreover have an obvious surjective homomorphism $\widehat{\mathfrak{S}}_{g,\nu} \longrightarrow \widehat{\widehat{\mathfrak{S}}}|\overline{\mathfrak{S}}_{g,\nu}$ whose image is $\overline{\mathfrak{S}}_{g,\nu}$, we shall admit that it is injective, and shall identify $\overline{\mathfrak{S}}_{g,\nu}$ with $\widehat{\mathfrak{S}}_{g,\nu}$. Thus

$$\text{Discrt}'(\pi) \simeq \text{Isom}_{\text{lac}}(\widehat{\Pi}_{g,\nu}, \pi)/\widehat{\mathfrak{S}}_{g,\nu} \tag{8}$$

Scans 321–330

[scan 321]

An element of Discrét$'(\pi)$ is called a class of discretifications of πor prediscretification of π[i1]. If π_0 is a discretification, we denote its class by $\pi_0^\natural$. The set of classes of discretifications on π is a homogeneous space under $\widehat{\widehat{\mathfrak{S}|\mathcal{G}}}(\pi)$, the stabilizer of $\pi_0^\natural$ is identified with|being identified with : the closure of $\mathfrak{S}|\mathcal{G}(\pi_0) = \text{Aut}_{\text{lac}}(\pi_0)$ in $\widehat{\widehat{\mathfrak{S}|\mathcal{G}}}(\pi)$, or again : $\widehat{\mathfrak{S}|\mathcal{G}}(\pi_0)$. The latter always contains π.

$$\text{Aut}_{\text{lac}}(\pi, \pi_0^\natural) \simeq \widehat{\mathfrak{S}|\mathcal{G}}(\pi_0)$$

[d1] for every discretification $\pi_0^\natural$, the subgroup of $\widehat{\widehat{\mathfrak{S}|\mathcal{G}}}(\pi)$ of loop automorphisms which fix $\pi_0^\natural$ is denoted $\widehat{\mathfrak{S}|\mathcal{G}}(\pi_0^\natural)$, it is therefore the inverse image of a subgroup of $\widehat{\widehat{\mathcal{T}}}(\pi)$, denoted $\widehat{\mathcal{T}}(\pi_0^\natural)$. We thus have an inclusion of extension structures

(10)

$$\begin{array}{ccccccccc} 1 & \longrightarrow & \pi & \longrightarrow & \widehat{\mathfrak{S}|\mathcal{G}}(\pi_0^\natural) & \longrightarrow & \widehat{\mathcal{T}}(\pi_0^\natural) & \longrightarrow & 1 \\ & & & & \downarrow & & \downarrow & & \\ 1 & \longrightarrow & \pi & \longrightarrow & \widehat{\widehat{\mathfrak{S}|\mathcal{G}}}(\pi) & \longrightarrow & \widehat{\widehat{\mathcal{T}}}(\pi) & \longrightarrow & 1 \end{array}$$

m438

Marginal note. [m438] N.B. The set of classes of discretifications of π is described [illeg. 2] of the outer group π, as $\mathrm{Isom\,ext}(\widehat{\Pi}_{g,\nu}, \pi)$[d2] divided by $\widehat{\mathcal{T}}_{g,\nu}$. We moreover have an arrow of degree 2

$$\begin{array}{c} \mathrm{Isom\,ext}(\widehat{\Pi}_{g,\nu}, \pi)/\widehat{\mathcal{T}}^{+}_{g,\nu} \\ \downarrow \\ \mathrm{Isom\,ext}(\widehat{\Pi}_{g,\nu}, \pi)/\widehat{\mathcal{T}}_{g,\nu} \end{array}$$

which makes it possible for every|the class of discretifications, to define its two orientations, and speak of oriented discretifications.

[p. 320]

[scan 322]

[p. 163]

(One shows by arithmetico-geometric means that the inclusion $\widehat{\mathcal{T}} \longrightarrow \widehat{\widehat{\mathcal{T}}}$ is never an isomorphism.) We thus find a map

$$\text{Discrét}'(\pi) \longrightarrow \text{Closed subgroups of } \widehat{\widehat{\mathcal{T}}}(\pi) \tag{11}$$

obviously compatible with the action of [d1] $\widehat{\widehat{\mathfrak{S}|\mathcal{G}}}(\pi)$ (transport of structure) – operating on the right via $\widehat{\widehat{\mathcal{T}}}(\pi)$ and its inner automorphisms on itself.

We thus find a conjugacy class, well determined of|of the closed subgroups of $\widehat{\widehat{\mathcal{T}}}(\pi)$, which we call its "geometric" Teichmüller subgroups. [d2] It could moreover be that $\widehat{\mathcal{T}}_{g,\nu}$ is its own normalizer in $\widehat{\widehat{\mathcal{T}}}_{g,\nu}$ – equivalent to the assertion that (11) is injective|bijective|injection : The datum of a class of discretificationsof π[i1] would be equivalent to that of a geometric Teichmüller subgroup in [d3] its extended Teichmüller group $\widehat{\widehat{\mathcal{T}}}$.

m439

Marginal note. m439 this is completely screwy and ultra-false – a moment of aberration ! This becomes clear in what follows…The sensible question (with which I must have at the time confused) is whether $\widehat{\mathcal{T}}$ is invariant in $\widehat{\widehat{\mathcal{T}}}$, i.e. whether the normalizer is $\widehat{\widehat{\mathcal{T}}}$ all|all of it !

[scan 324]

[p. 164]

there is only a single and unique one!) will be called the strict geometric Teichmüller subgroups. The choice of such a subgroup of $\widehat{\widehat{\mathcal{T}}}$ [i1] is, in any case, an element of structure distinctly weaker than that of a class of discretifications, and even than that of a geometric Teichmüller subgroup (not strict).

To specify the relations between these two notions, let us first recall that $\widehat{\mathcal{T}}^+ = \Sigma$ is deduced from $\widehat{\mathcal{T}}$ as the kernel of $\chi \mid \widehat{\mathcal{T}} : \widehat{\mathcal{T}} \longrightarrow \{\pm 1\}$. On the other hand, [d1] (for a chosen strict geometric Teichmüller subgroup $\widehat{\mathcal{T}}^+$) let us consider

$$(14) \qquad \mathcal{N}|N_\Sigma = \mathcal{N} = \mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}}(\Sigma) \qquad (\Sigma = \widehat{\mathcal{T}}^+)$$

(perhaps always equal to all of $\widehat{\widehat{\mathcal{T}}}$)

obviously (if Σ comes from a $\widehat{\mathcal{T}}$)

$$(15) \qquad \underset{=\widehat{\mathcal{T}}^+}{\Sigma} \subset \widehat{\mathcal{T}} \subset \mathcal{N}_\Sigma.$$

[d5] The profinite group $\mathcal{N}/\Sigma$ [d7] associated with [d8] Σ is denoted $\mathbf{\Gamma}_\Sigma$ [d11] [d12] (if Σ is unique, we write $\mathbf{\Gamma}_\pi$);

[scan 325]

and the $\widehat{\mathcal{T}}$ giving rise to the same Σ correspond [d3] to a conjugacy class of elements of order

2 of $\mathbf{\Gamma}_\Sigma$. It is clear [d5] in any case that we have an injective map

$$(16)\qquad \begin{array}{c}\text{set of geometric}\\ \text{Teichmüller subgroups}\\ \widehat{\mathcal{T}} \text{ of } \widehat{\widehat{\mathcal{T}}} \text{ such that}\\ \widehat{\mathcal{T}}^+ = \Sigma\end{array} \longrightarrow \begin{array}{c}\text{set of elements|elements}\\ \text{of order 2 of } \mathbf{\Gamma}_\Sigma\end{array} \quad :$$

and that its image is stable under conjugation. Let us show that two|the elements of the image are conjugate under $\mathbf{\Gamma}_\Sigma$. Indeed, let

$$\widehat{\mathcal{T}},\ \widehat{\mathcal{T}}' \supset \Sigma \quad \text{such that} \quad \Sigma = \widehat{\mathcal{T}}^+ = \widehat{\mathcal{T}}'^+.$$

[d6] $\exists\, g \in \widehat{\widehat{\mathcal{T}}}$[13] such that $\widehat{\mathcal{T}}' = \mathrm{int}(g)\mathcal{T}$, and we will have|have therefore $\widehat{\mathcal{T}}'^+ = \mathrm{int}_g \widehat{\mathcal{T}}^+$ i.e. $g \in \mathcal{N}$, OK.

The elements of order 2 thus obtained in $\mathbf{\Gamma}_\Sigma$ are called the canonical involutions. We will give a remarkable conjectural interpretation of them below. The set $\widehat{\widehat{\mathcal{T}}}/\mathcal{N}$ is identified with the set of subgroups of

[scan 326]

[p. 165]

strict geometric Teichmüller (once the "origin" element Σ has been chosen). More intrinsically, we will have:

$$(17)\qquad \begin{array}{l}\text{Set of strict geometric}\\ \text{Teichmüller subgroups}\end{array}\overset{\sim}{\leftarrow} | \simeq \mathrm{Isomext}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu},\pi)/\mathcal{N}_{g,\nu}$$
$$\text{of } \widehat{\mathcal{T}}(\pi)$$

where we set, as is only right

$$(18)\qquad \mathcal{N}_{g,\nu} = \mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}_{g,\nu}}(\widehat{\mathcal{T}}^{+}_{g,\nu})$$

(perhaps equal to all of $\widehat{\widehat{\mathcal{T}}}_{g,\nu}$!)

Let us now consider the modular topos over $\mathbb{Q}$ of algebraic curves of type (g,ν), denoted $M_{g,\nu\mathbb{Q}}$, or simply $M_{g,\nu}$. If we choose a universal covering $\widetilde{M}_{g,\nu}$ of $M_{g,\nu\mathbb{Q}}$ (hence a universal covering of $\mathrm{Spec}\mathbb{Q}$ i.e. an algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$) we can specify the $\pi_1(M_{g,\nu\mathbb{Q}})$ as the group of $M_{g,\nu\mathbb{Q}}$-automorphisms of this covering|covering; [d1] call it the[i1] arithmetic Teichmüller group of type (g,ν) (relative to the choice of $\widetilde{M}_{g,\nu\mathbb{Q}}$). We will thus have an exact sequence

[p. 325]

Apparatus for this scan

whose indeterminacy we would like to determine precisely

Let $M_{g,\nu C}$ denote the complex modular Teichmüller [d2]topos[i1], defined using the [d3]C^{∞}[i2] surface $U|\mathcal{U}_{g,\nu}$, it is equipped with the canonical universal covering $\widetilde{M}_{g,\nu C}$ (§ 21) [m441]

Marginal note. [m441] $\widetilde{M}_{g,\nu C} = E_g/A^0_{g,\nu}|A^{\circ}_{g,\nu}$

with group of automorphisms $\mathcal{T}^+_{g,\nu}$ precisely –|... $U|\mathcal{U}_{g,\nu C}$ being itself also equipped with a universal covering over the preceding one, $\widetilde{U|\mathcal{U}}_{g,\nu C} = E_g/A^0_{g,\nu+1}|A^{\circ}_{g,\nu+1}$. This gives rise to the exact sequence of discrete groups (in the general topology context)

$$\begin{array}{lccccccc}
(24) & 1 \to \Pi_{g,\nu} & \longrightarrow & \mathfrak{S}|\mathcal{G}^+_{g,\nu} & \longrightarrow & \mathcal{T}^+_{g,\nu} & \longrightarrow & 1 \\
 & \downarrow & & \| & & \| & & \\
 & & & \pi_1(U|\mathcal{U}_{g,\nu C}) & & \pi_1(M_{g,\nu C}) & & \\
 & & & \downarrow & & \downarrow & & \\
\text{(mapping to} & 1 \to \Pi_{g,\nu} \to & & \mathrm{Aut}_{\mathrm{lac}}(\Pi_{g,\nu}) & \to & \mathrm{Aut}\,\mathrm{ext}_{\mathrm{lac}}(\Pi_{g,\nu}) & \to & 1 \\
 & & & \| & & \| & & \\
 & & & \mathfrak{S}|\mathcal{G}_{g,\nu} & & \mathcal{T}_{g,\nu} & &
\end{array}$$

by an isomorphism|homomorphism of extension structures), which by passage to the profinite completions gives the analogous exact sequence for the

[scan 329]

algebraic multiplicities over $\mathbb{C}$

$$(25)\qquad \begin{array}{ccccccc} 1 & \to & \widehat{\Pi}_{g,\nu} & \longrightarrow & \widehat{\mathcal{G}}_{g,\nu} & \longrightarrow & \widehat{\mathcal{T}}^{+}_{g,\nu} \longrightarrow 1 \\ & & \| & & \downarrow & & \updownarrow \\ & & \widehat{\Pi}_{g,\nu} & \longrightarrow & \mathrm{Aut}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu}) & \longrightarrow & \mathrm{Autext}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu}) \\ & & & & \backslash\backslash\, \widehat{\widehat{\mathcal{G}}}_{g,\nu} & & \backslash\backslash\, \widehat{\widehat{\mathcal{T}}}_{g,\nu} \end{array}$$

This situation moreover arises canonically from an analogous situation over $\overline{\mathbb{Q}}_0$ = algebraic closure of $\mathbb{Q}$ in $\mathbb{C}$, the choice of $\widetilde{U|\mathcal{U}}_{g,\nu\mathbb{C}}$ defining a $\widetilde{U|\mathcal{U}}_{g,\nu\overline{\mathbb{Q}}_0}$, hence a $\widetilde{M}_{g,\nu\overline{\mathbb{Q}}_0}$.

To define an isomorphism between this sequence (25) and the exact sequence $(\overline{21})$ [d3] (equipped with 2 homomorphisms|its homomorphism to (22)) one must

1°) choose an isomorphism $\overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}_0$ — the indeterminacy is in $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$; which makes it possible to identify $\overline{\mathbb{Q}}$ and $\overline{\mathbb{Q}}_0$;

2°) Choose an isomorphism ([d4] $\overline{\mathbb{Q}} = \overline{\mathbb{Q}}_0$) of $(\widetilde{U|\mathcal{U}}_{g,\nu})_0$ (constructed by transcendental|transcendental means over $\mathbb{C}$ and descended to $\overline{\mathbb{Q}}_0$) with $\widetilde{U|\mathcal{U}}_{g,\nu\overline{\mathbb{Q}}}$ — the indeterminacy is in $\pi_1(M_{g,\nu\overline{\mathbb{Q}}})$.

In summary, we have a class of isomorphisms of (24)|(21)2|?[i6] and (25), defined modulo automorphisms [d5] [illeg. 1] once we have chosen $\overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}_0$ [i7] inner in the profinite group[i8] $\pi_1(U|\mathcal{U}_{g,\nu})$. (These|The corresponding[i9] isomorphisms transform the [d6] Standard|standard oriented class of discretification of $\widehat{\Pi}_{g,\nu}$ into [d7] exactly[i10] one class of oriented discretifications of π.

[scan 332]

[p. 168]

The natural conjecture here is that

$$\text{(27)} \qquad \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \longrightarrow \Gamma_\Sigma$$

from the Galois group to the arithmetic outer automorphisms of (π, Σ) is an isomorphism. We can supplement it by the conjecture, still bolder, that moreover Σ is invariant in $\widehat{\mathcal{T}}(\pi)$ ($\Longleftrightarrow$ $\Sigma_{g,\nu}$ invariant in $\widehat{\mathcal{T}}_{g,\nu}$), which would thus mean that $\mathcal{N}|N_\Sigma = \widehat{\mathcal{T}}$, or again that [d1] Conjectural!!

$$\text{(28)} \qquad \pi_1(M_{g,\nu}) \xrightarrow{\sim} \widehat{\mathcal{T}}(\pi) = \mathrm{Aut}\,\mathrm{ext}_{\mathrm{lac}}(\pi).$$

and $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ would be identified with the "arithmetic" quotient of the group of outer loop automorphisms of π.

Let now U be an algebraic curve of type g, ν over $\overline{\mathbb{Q}}$. It is defined by a point of $M_{g,\nu\overline{\mathbb{Q}}}$ over $\mathrm{Spec}\,\overline{\mathbb{Q}}$, and [d2] as the fiber of $\mathcal{U}_{g,\nu}$ at this point. Let us choose a universal covering of U, whence a group $\pi(U)$, canonically isomorphic to the group π a-

bove, once an isomorphism has been chosen between $\widetilde{\mathcal{U}}_{g,\nu}$ and the universal covering of $\mathcal{U}_{g,\nu}$ deduced from $\widetilde{U}$, which gives an indeterminacy in $\pi_1(\mathcal{U}_{g,\nu\overline{\mathbb{Q}}}) \simeq \hat{\mathcal{S}}^+$.

Thus, once an isomorphism $\overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}_0$ has been chosen, one finds on $\pi_1(U)$ an oriented quasi-discretification (obvious moreover to define directly, by transcendental means) changed into its opposite by changing the isomorphism $\overline{\mathbb{Q}}_2|\overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}_0$ by complex conjugation. On the other hand, the subgroup $\widehat{\mathcal{T}}^+$ of $\widehat{\mathcal{T}}(\pi)$ corresponding to this quasi-discretification (oriented, little do we care) does not depend on the choice of the isomorphism in question $\overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}_0$, it is canonically associated with π as the fundamental group of a U over [d1] an algebraically closed field

[N.B. one could take any algebraically closed field of characteristic 0, no need for it to be a|over[i1] $\overline{\mathbb{Q}}$, cf. below].

with the set $(\subset \mathrm{Isom}(\widehat{\Pi}_{g,\nu}, \pi)/\widehat{\mathcal{T}}^0_{g,\nu}$ [i1] of [d1] oriented quasi-rigidifications giving rise to $\pi_{g,\nu}|\Pi_{g,\nu})$ and of a universal covering of $\mathcal{U}_{g,\nu\overline{\mathbb{Q}}}$ — or simply, of a universal covering $\widetilde{\mathcal{U}}_{g,\nu}$ of $\mathcal{U}_{g,\nu} = \mathcal{U}_{g,\nu\mathbb{Q}}$.

m444

Marginal note. [m444] If one gives oneself only π as an outer group, with Σ, this amounts to the datum of a universal covering of $M_{g,\nu}$.

The datum of an isomorphism $\overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}_0$ thus amounts to that of an oriented quasi-rigidification on π compatible with Σ (condition perhaps automatically satisfied…). [m445]

Marginal note. [m445] N.B. If one gives up choosing $\widetilde{U}$, this is equivalent|amounts to working with outer groups with loops.

That said, the datum of an algebraic curve of type g,ν[i2] over [d2i3] [d3] an algebraically closed field $\overline{\mathbb{Q}}$, and of a universal covering [d4] of it would amount to the datum of a preceding datum (namely [d5] a universal covering of an $M_{g,\nu}$[i4]), plus a point of $M_{g,\nu,\overline{\mathbb{Q}}}$ over $\overline{\mathbb{Q}}$ [d6] defining this universal covering — and,[i5] this last datum would be identified with a [d7] germ of splitting of the extension

$$1 \longrightarrow \pi_1(M_{g,\nu\overline{\mathbb{Q}}}) \longrightarrow \pi_1(M_{g,\nu}) \longrightarrow \pi_1(\mathbb{Q}) \longrightarrow 1$$

[i6] The profinite[i7] interpretation (in terms of the outer groups with loops π)[i8] is then[i9] [d8] a (π, Σ), and a germ of splitting of

$$1 \longrightarrow \Sigma \longrightarrow N_\Sigma \longrightarrow \Gamma_\Sigma \longrightarrow 1.$$

If one wants a curve over a finite subextension K' of $\overline{\mathbb{Q}}/\mathbb{Q}$, corresponding to a subgroup of finite index $\Gamma' \subset \Gamma_\Sigma$, it will be a matter of a partial [d9] splitting $\Gamma' \longrightarrow N_\Sigma$.

[p. 170]

But surely, if this [d1] description[i1] of anabelian algebraic curves is fully faithful, it is not 2-faithful, i.e. conditions on a splitting are needed, which will have to be examined later.

The description of an [d2] algebraic curve of type g, ν over an arbitrary fixed[i2] field of finite type , characteristic 0|over $\mathbb{Q}$[i3] K, endowed with an algebraically closed extension $\overline{K}$ (thus $\Gamma = \mathrm{Gal}\,\overline{K}/K' \longrightarrow \Gamma_0 = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, where $\overline{\mathbb{Q}}$ is the algebraic closure of $\mathbb{Q}$ in $\overline{K}$), in terms of $\Gamma \longrightarrow \Gamma_0$, would be the following: datum of an outer group with loops π of type g, ν, of a Teichmüller subgroup Σ in $\widehat{\widehat{\mathcal{T}}}(\pi)$, of an isomorphism $\overline{\mathbb{Q}} \simeq$ field defined by this situation (having as Galois group [d3] N_Σ/Σ, so that we find an isomorphism $\Gamma_0 \simeq N_\Sigma/\Sigma$) finally of a lifting of $\Gamma \longrightarrow \Gamma_0$ [d4] (which describes[i4] an arithmetically outer action of Γ on (π, Σ)) into an outer action $\Gamma \longrightarrow N_\Sigma$ of Γ on (π, Σ) ; with conditions which one will have to try

to bring out (necessary and sufficient conjecturally) on this lifting.

[d1] Let us note that every embedding $\overline{K} \subset \mathbb{C}$ defines canonically|canonically[i1] on the outer group $\pi = \pi_1(U_{\overline{K}})$ an oriented quasi-discretification, replaced by the opposite when the embedding is replaced by its complex conjugate. [d2] [d3] I say that these quasi-discretifications all define Σ as the group of automorphisms, and that the quasi-discretification defined by $\overline{K} \hookrightarrow \mathbb{C}$ depends only on its restriction to $\overline{\mathbb{Q}} \subset \mathbb{C}$ — in a more precise way, it is the one one defines directly with the help of $\overline{\mathbb{Q}} \subset \mathbb{C}$ i.e. of $\overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}_0$ — But there is reason also to examine the way to obtain discretifications. Thus, if one has a|a[i2] U is defined over $\overline{\mathbb{Q}}_0$ (i.e. an outer $\pi|\Pi$ of type (g, ν), endowed with an oriented quasi-discretification

[scan 339]

I refer to the beginning of the following § (§ 27) for the change in terminology, "quasi-discretification" becoming a "prediscretification". But there is reason also to introduce a finer notion, corresponding — to the [illeg. 1] π_1 (profinite) of an algebraic variety X defined over an algebraically closed field $\overline{K}$, when one embeds $\overline{K}$ into $\mathbb{C}$: there is a discretification modulo inner automorphisms|automorphisms — we shall call it a strict prediscretification. In the case of a π with loops, the homogeneous [d1] [d2] in $\widehat{\widehat{\mathcal{T}}}(\pi)$ of this is identified with

$$\mathrm{Isom}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu}, \pi)/\widehat{\Pi}_{g,\nu} \cdot \mathcal{T}_{g,\nu} \simeq \mathrm{Isom}\,\mathrm{ext}_{\mathrm{lac}}(\widehat{\Pi}_{g,\nu}, \pi)/\mathcal{T}_{g,\nu}$$

— this notion also|also[i2] depends only on the outer profinite group with loops defined by $\Pi_{g,\nu}$), and [d4] is equivalent to that of an "outer basis" in π modulo the action of $\mathcal{T}_{g,\nu}$,[i3] i.e. of an isomorphism[i4] of π with the "standard" $\widehat{\Pi}_{g,\nu}$; modulo the action of $\mathcal{T}_{g,\nu}$.[i5] The map

$$\text{Outer bases of } \pi \longrightarrow \text{Prediscretifications of } (\pi)$$

makes therefore of the left-hand side a relative torsor on the right,[i7] over the one on the right, under the group $\mathcal{T}_{g,\nu}$. [d6]

A prediscretification of (π, Σ) corresponds to a choice of an isomorphism of the algebraic closure $\overline{\mathbb{Q}}_{(\pi,\Sigma)} = \overline{\mathbb{Q}}$[i8] associated with (π, Σ), with $\overline{\mathbb{Q}}_0$. When one has given (π, Σ) as corresponding to an algebraic curve over $\overline{\mathbb{Q}}$, i.e. that one gives oneself|has given oneself a germ of liftings of Γ_Σ into $N_\Sigma \subset \widehat{\widehat{\mathcal{T}}}(\pi)$ i.e. a germ|group of outer action of Γ_Σ on π, every|whose prediscretification must[i9] give rise to a strict discretification — and a[i10] [d7] discretification is equivalent on lifting back a germ of action ("admissible") of Γ_Σ on π …

[p. 172]

27. Change of type (g, ν) : a) plugging holes.

I am going to change terminology, calling prediscretification what I had called (a little pejoratively !) quasi-discretification. Indeed, we foresee that a prediscretification — compatible with Σ —)[i1] (which amounts morally|morally to the embedding (modulo complex conjugation)[i2] into $\mathbb{C}$ of the algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$ canonically associated with|$*$ $(\pi, \Sigma(\subset \widehat{\widehat{\mathcal{T}}}(\pi)))$, gives rise as soon as the outer-arithmetic action of $\Gamma_\Sigma = N_\Sigma/\Sigma$ on π is lifted to a germ of action on π, to a genuine discretification of π. Ditto|The same for oriented prediscretifications. The group N_Σ/Σ deserves [m446]

Marginal note. [m446] morally|normally, $\Sigma = \widehat{\mathcal{T}}$ (but there is no $\mathcal{T}$!)

a name as well — I am going to call it the arithmetic Teichmüller group associated with (π, Σ), and its elements will be called the arithmetically outer automorphisms of π — deduced from an outer automorphism (normalizing Σ) : by disregarding the "geometric" outer automorphisms (i.e. precisely those $\in \Sigma$) — [d1] as the ordinary[i3] outer automorphisms were described by disregarding the inner automorphisms of π. We [d2] shall note that the "multiplier" character

$$\chi : \widehat{\widehat{\mathcal{T}}}(\pi) \longrightarrow \widehat{\mathbb{Z}}^*$$

is trivial on Σ, by construction of Σ, and passes to Γ_Σ

$$\chi_\Sigma : \Gamma_\Sigma \longrightarrow \widehat{\mathbb{Z}}^*$$

Scans 341–350

[scan 341]

Of course, this character will again be called, "multiplier", and|or "cyclotomic character". [d1] If our fundamental conjecture is true, this character identifies $(\Gamma_\Sigma)_{\mathrm{ab}}$ with $\widehat{\mathbb{Z}}^*$.

On the other hand, if $I = I(\pi)$, the canonical homomorphism

$$\widehat{\widehat{\mathcal{T}}} \longrightarrow \mathfrak{S}_I | \mathcal{S}_I$$

is [d2] not trivial on Σ, but induces a surjective homomorphism

$$\Sigma \longrightarrow \mathfrak{S}_I$$

whence a subgroup $\Sigma^!$ such that

$$\Sigma/\Sigma^! \xrightarrow{\sim} \mathfrak{S}_I.$$

We see at once that $\forall\ \gamma | g \in \widehat{\widehat{\mathcal{T}}}$ which normalizes Σ normalizes $\Sigma^! = \Sigma \cap \widehat{\widehat{\mathcal{T}}}^!$, whence|i.e. $\Sigma^!$ is also invariant in $\mathcal{N}_\Sigma$. [d4] Let $\mathcal{N}^!_\Sigma = \mathcal{N}_\Sigma \cap \widehat{\widehat{\mathcal{T}}}^!$, we have a Cartesian diagram of subgroups of $\widehat{\widehat{\mathcal{T}}}$

morally, $\Sigma^! \simeq \widehat{\mathcal{T}}^{!+}$

$$\begin{array}{ccc} \mathcal{N}^! & \xhookrightarrow{\mathfrak{S}_I} & \mathcal{N} \\ {\scriptstyle \Gamma_\Sigma}\uparrow & & \uparrow{\scriptstyle \Gamma_\Sigma} \\ \Sigma^! & \xhookrightarrow[\mathfrak{S}_I]{} & \Sigma \end{array}$$

giving an injective homomorphism

$$\mathcal{N}/\Sigma^! \longrightarrow \underbrace{\mathcal{N}/\mathcal{N}^!}_{\mathfrak{S}_I} \times \underbrace{\mathcal{N}/\Sigma}_{\Gamma_\Sigma}$$

of which|when we see at once that it is bijective [m448]

Marginal note. [m448] and|for $\Sigma/\Sigma^! \xrightarrow{\sim} \mathcal{N}/\mathcal{N}^!$ $(\simeq \mathfrak{S}_I)$

$$\mathcal{N}/\Sigma^! \xrightarrow{\sim} \mathcal{N}/\mathcal{N}^! \times \mathcal{N}/\Sigma \simeq \mathfrak{S}_I \times \Gamma_\Sigma$$

and consequently we also have

$$\mathcal{N}^!/\Sigma^! \xrightarrow{\sim} \mathcal{N}/\Sigma = \Gamma_\Sigma,$$

i.e. the group Γ_Σ of arithmetically outer automorphisms of (π, Σ) can also be described via the automorphisms [p. 340]

[scan 342]

[p. 173]

that are outer and induce the identity on I.

In the case $(g,\nu)=(0,3)$, we have $\Sigma^!=(1)$, $\Rightarrow$ hence $\Sigma \overset{\sim}{\to} \mathfrak{S}_3$. $\mathcal{N}$ is the [d1] normalizer of $\mathfrak{S}_3$ in $\widehat{\widehat{\mathcal{T}}}$, $\mathcal{N}^! \overset{\sim}{\to}\Gamma_\Sigma$[i1] is its centralizer, and $\mathcal{N}$ is identified with the direct product of the two.
[d2]

Now let $I|I' \subset I$, $\nu' = \operatorname{card} I'$,[i2] and let us consider the outer group π' obtained from π by "plugging the holes at $I \setminus I'$", whence a homomorphism

$$\pi^* \longrightarrow \pi'.$$

[d3] Let us consider[i3] the bases of π,[i4] for which [d4] [d5] the ν' [d6] first[i6] l_i,[i5] are in [d7i7] groups with loops [d8] $L_{i'}$ $(i' \in I')$ — we call them adapted to I'; they form a torsor $\subset \operatorname{Isom}_{\text{lac}}(\hat{\pi}_{g,\nu}, \pi)$[i8] under the subgroup of [d9] $\widehat{\widehat{\mathcal{G}}}_{g;(\nu,\nu')}$ of $\widehat{\widehat{\mathcal{G}}}_{g,\nu} = \operatorname{Aut}_{\text{lac}}(\hat{\pi}_{g,\nu})$[i9] consisting[i10] of the $u|h \in \widehat{\widehat{\mathcal{G}}}_{g,\nu}$ whose image in $\mathfrak{S}_I$ leaves invariant [d12] the set[i11] of the ν' first elements (or, of the $\nu-\nu'$ last its|their complementary set,[i12]).
m449

Marginal note. [m449] Whence also: $\forall$ basis, $\forall$ discretification, oriented discretification of π defines one of π', whence ditto for classes of π, π'[i13] conjugation, i.e. for|by the strict prediscretifications (possibly oriented)[i14], and also for|by the closures of the classes, i.e. the [d14] prediscretifications and oriented prediscretifications. It is only the case of arithmetizations|arithmetizations that [d15] would require[i15] a finer analysis…

For such a basis, we find a corresponding basis of π'. [d16] The datum of (π, I') is equivalent to that of a torsor under $\widehat{\widehat{\mathcal{G}}}_{g,(\nu,\nu')}$, that of a π' to [d18] the datum of a torsor under $\widehat{\widehat{\mathcal{G}}}_{g,\nu'}$, and the passage from π to π' is described by the change of group of operators

$$\widehat{\widehat{\mathcal{G}}}_{g,(\nu,\nu')} \longrightarrow \widehat{\widehat{\mathcal{G}}}_{g,\nu'}$$

this homomorphism sends $\widehat{\mathcal{G}}_{g,(\nu,\nu')} = \Sigma_{g,(\nu,\nu')}$ into $\widehat{\mathcal{G}}_{g,\nu'} = \Sigma_{g,\nu'}$, [p. 341]

$\Sigma_{g,\nu}$ (intersection)

and even[i1] $\mathcal{G}_{g,(\nu,\nu')}$ into $\mathcal{G}_{g,\nu'}$, also π into π'. It follows that every prediscretification of π defines one of π', the same for strict prediscretifications, [d1] discretifications, outer bases "adapted to I'" [d2i2]. Finally, if we have a "prearithmetization" of π, i.e. a $\Sigma \subset \widehat{\widehat{\mathcal{T}}}(\pi)$, do we deduce from it a prearithmetization of π' — i.e. (for example)[i3] if two prediscretifications of π are compatible i.e. [d3] have the same group $\Sigma \subset \widehat{\widehat{\mathcal{T}}}(\pi)$, of outer automorphisms, is the same true of their images? [d4]

To see more clearly, we are going to write in diagram form the remarkable sets associated with π, and this in two ways, one without using any particular structure|particular structures on $I = I(\pi)$, the other using a total order, which makes it possible, in the torsor $\mathrm{Isom}_{\mathrm{lac}}(\hat{\pi}_{g,\nu}, \pi)$ under $\widehat{\widehat{\mathcal{G}}}_{g,\nu}$, to define the subtorsor under $\widehat{\widehat{\mathcal{G}}}^{!}_{g,\nu}$ which we may denote [d5] $\mathrm{Isom}^{!}_{\mathrm{lac}}(\hat{\pi}_{g,\nu}, \pi)$. N.B.

We set [d1]

$$\Gamma_{g,\nu} = \mathcal{N}_{g,\nu}/\Sigma_{g,\nu} = \mathcal{N}^{!}_{g,\nu}/\Sigma^{!}_{g,\nu}$$

(where $\Sigma_{g,\nu} = \widehat{\mathcal{T}}^{+}_{g,\nu}$, $\Sigma^{!}_{g,\nu} = \widehat{\mathcal{T}}^{!+}_{g,\nu}$). We can also describe it as the group Γ_Σ associated with a profinite outer[i1] group with loops π[i2] equipped with an oriented[i3] prediscretification α (nothing more). If we have two such [d2]pairs[i4] $(\pi, \alpha), (\pi', \alpha')$, whence Γ_Σ and $\Gamma_{\Sigma'}$ ($\Sigma = \mathrm{Aut}\,\mathrm{ext}_{\mathrm{lac}}(\pi, \alpha)$, $\Sigma' = \mathrm{Aut}\,\mathrm{ext}_{\mathrm{lac}}(\pi', \alpha')$), we indeed find a canonical isomorphism

$$\Gamma_\Sigma \xrightarrow{\sim} \Gamma_{\Sigma'}$$

by taking any outer isomorphism with loops u[i5] of π with π', transforming α into α' — the associated isomorphism $\Gamma_\Sigma \longrightarrow \Gamma_{\Sigma'}$ obviously does not depend on the choice of u.

This being said, the pairs (π, Σ) of a[i6] profinite|profinite group|groups with loops of type (g, ν), [d3]equipped with a[i7] prearithmetization, with as morphisms the arithmetically outer isomorphisms [d4](relative to[i8] Σ and Σ' ...), form a connected groupoid $\Pi_{g,\nu}$, having an "origin" object (defined up to unique isomorphism as being $(\hat{\pi}_{g,\nu}, \Sigma_{g,\nu})$, or at will any (π, Σ_α) coming from a (π, α) (α an oriented prediscretification of π), and whose group of automorphisms is precisely $\Gamma_{g,\nu}$. [p. 175]

We observe that, with the exception of the two homogeneous spaces (under $\widehat{\widehat{\mathcal{G}}}(\pi)$, but not necessarily|necessarily under $\widehat{\widehat{\mathcal{G}}}(\pi, I')$, or even under $\widehat{\widehat{\mathcal{G}}}^!(\pi)$) Bases (π) and Outer bases (π), the other four are in fact homogeneous spaces under $\widehat{\widehat{\mathcal{G}}}^!$, and are expressed as quotients of the $\widehat{\widehat{\mathcal{G}}}^!_{g,\nu}$-[i1]torsor $\mathrm{Isom}^!(\hat{\pi}_{g,\nu}, \pi)$, by the four subgroups

$$\mathcal{G}^!_{g,\nu}, \quad \mathcal{G}^!_{g,\nu} \cdot \hat{\pi}_{g,\nu}, \quad \widehat{\mathcal{G}}^!_{g,\nu}, \quad \mathcal{M}^!_{g,\nu}$$

(the last defined as the inverse image of $\mathcal{N}^!_{g,\nu}$ in $\widehat{\widehat{\mathcal{G}}}_{g,\nu}$, just as $\mathcal{M}_{g,\nu}$ is defined as the inverse image of $\mathcal{N}_{g,\nu}$). We find on the other hand, if|for $I' = \{i_0, \dots, i_{\nu'-1}\}$, a|some homomorphism

$$\widehat{\widehat{\mathcal{G}}}^!_{g,\nu} \longrightarrow \widehat{\widehat{\mathcal{G}}}^!_{g,\nu'},$$

sending $\mathcal{G}^!_{g,\nu}$ into $\mathcal{G}^!_{g,\nu'}$, [d1] by sending $\pi_{g,\nu}$ into $\pi_{g,\nu'}$, thus $\hat{\pi}_{g,\nu}$ into $\hat{\pi}_{g,\nu'}$, $\widehat{\mathcal{G}}^!_{g,\nu} = \Sigma^!_{g,\nu}$ into $\widehat{\mathcal{G}}^!_{g,\nu'} = \Sigma^!_{g,\nu'}$, and the subgroup $\mathcal{G}^!_{g,\nu} \cdot \hat{\pi}_{g,\nu}$ of [d2] $\widehat{\mathcal{G}}^!_{g,\nu}$[i2] into the subgroup $\mathcal{G}^!_{g,\nu'} \cdot \hat{\pi}_{g,\nu'}$ of $\widehat{\mathcal{G}}^!_{g,\nu'}$. Finally, since $\Sigma^!_{g,\nu}$ maps into $\Sigma^!_{g,\nu'}$, [d3] $\mathcal{N}^!_{g,\nu}$ maps into the normalizer of $\Sigma^!_{g,\nu'}$ (in $\widehat{\widehat{\mathcal{T}}}^!_{g,\nu'}$)[i3], [d4]I say that this[i4] is none other than $\mathcal{N}^!_{g,\nu'}$. Changing notation, this amounts to the

Lemma The $\mathcal{N}^!_\Sigma = \mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}^!}(\Sigma^!)$ [d5] $(= \mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}}(\Sigma^!) \cap \widehat{\widehat{\mathcal{T}}}^!)$. not proved [d6]

Obviously we have $\mathcal{N}^!_\Sigma \subset \mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}}(\Sigma^!) \cap \widehat{\widehat{\mathcal{T}}}^!$, conversely let $g \in \widehat{\widehat{\mathcal{T}}}^!$ which normalizes $\Sigma^!$, let us show that it normalizes Σ i.e. that it is $\in \mathcal{N}$ (thus $\in \mathcal{N}^! = \mathcal{N} \cap \widehat{\widehat{\mathcal{T}}}^!$). [scan 347]

It's not clear. I nevertheless[i1] feel like proving|pronouncing [d1] the conjecture The canonical map

$$\text{Prediscretifications|Prediscretifications}^{+}(\pi) \xrightarrow{\sim} \text{Prediscretifications|Prediscretifications}^{+}(\pi')$$

is bijective. In order that[i2] two oriented prediscretifications α, β of π [d2] have the same group of outer automorphisms $\Sigma_\alpha = \Sigma_\beta$, [d3] it is necessary and sufficient [d4] that it be so.[i3] for their images $\Sigma_{\alpha'}$ and $\Sigma_{\beta'}$, i.e. that $\Sigma_{\alpha'} = \Sigma_{\beta'}$; so that the preceding bijection induces a bijection

$$\text{Prearithmetizations}(\pi) \xrightarrow{\sim} \text{Prearithmetizations}(\pi').$$

Finally, [d5] the preceding bijections are compatible with[i4] the homomorphism of the groups of operators[i5] $\widehat{\widehat{\mathcal{T}}}(\pi, I') \longrightarrow \widehat{\widehat{\mathcal{T}}}(\pi')$, [d6] a fortiori[i6] a $\widehat{\widehat{\mathcal{T}}}^{!}(\pi) \longrightarrow \widehat{\widehat{\mathcal{T}}}^{!}(\pi')$, [d7] which implies that it thereby induces|that it induces them (for a given prearithmetization $\Sigma \subset \widehat{\widehat{\mathcal{T}}}(\pi)$[i7] of π, giving Σ' $\subset \widehat{\widehat{\mathcal{T}}}(\pi')$[i8] in π'; with $\Sigma^{!} \longrightarrow \Sigma'^{!}$[i9]) a homomorphism $\mathcal{N}^{!}_{\Sigma} \longrightarrow \mathcal{N}^{!}_{\Sigma'}$, [d10] and the corresponding homomorphism

$$\Gamma_\Sigma = \mathcal{N}^{!}_{\Sigma}/\Sigma^{!} \longrightarrow \Gamma_{\Sigma'} = \mathcal{N}^{!}_{\Sigma'}/\Sigma'^{!}$$

is an isomorphism.

To convince oneself of this it suffices to look at [d13] (choosing $\pi = \pi_{g,\nu}|\hat{\pi}_{g,\nu}$, I' [d14] reduced to the|being a last element|element of I_ν)[i10] the case where $I' = \{i'|i\}$, We then have a homomorphism

$$\widehat{\widehat{\mathcal{T}}}(\pi, i) \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi').$$

(the outer loop automorphisms of π fixing i define well-determined automorphisms of π' — not just outer ones) [p. 346]

[scan 348]

[p. 176]

i.e. $\widehat{\widehat{\mathcal{G}}}(\pi, i) \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi')$ is trivial on $\widehat{\pi}$, and thus passes to the quotient as a $\widehat{\widehat{\mathcal{T}}}(\pi, i) \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi, i)$. I assume, [d1] by analogy with the discrete case, that this homomorphism is an isomorphism, so that we have an exact sequence [m457]

Marginal note. [m457]

m458

Marginal note. [m458] recall that we assume π anabelian|nonabelian $(2g + \nu \geq 3)$

$$1 \longrightarrow \pi' \longrightarrow \widehat{\widehat{\mathcal{T}}}(\pi, i) \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi', i) \longrightarrow 1$$

or again

$$1 \longrightarrow \hat{\pi}_{g,\nu-1} \longrightarrow \widehat{\widehat{\mathcal{T}}}_{g,(\nu,\nu-1)} \longrightarrow \widehat{\widehat{\mathcal{G}}}_{g,\nu-1} \longrightarrow 1$$

which contains the exact sequence

$$1 \longrightarrow \pi^{*|+}_{g,\nu-1} \longrightarrow \mathcal{T}_{g,(\nu,\nu-1)} \longrightarrow \mathcal{G}_{g,\nu-1} \longrightarrow 1$$

as|known sub[d2], sequence|is exact. It is convenient to work instead with

$$\begin{array}{ccccccccc}
1 & \longrightarrow & \pi_{g,\nu-1} & \longrightarrow & \mathcal{T}^{!+}_{g,\nu} & \longrightarrow & \mathcal{G}^{!+}_{g,\nu-1} & \longrightarrow & 1 \\
 & & \uparrow & & \uparrow & & \uparrow & & \\
1 & \longrightarrow & \hat{\pi}_{g,\nu-1} & \longrightarrow & \widehat{\mathcal{T}}^{!+}_{g,\nu} & \longrightarrow & \widehat{\mathcal{G}}^{!+}_{g,\nu-1} & \longrightarrow & 1 \\
 & & \| & & \uparrow & & \downarrow & & \\
1 & \longrightarrow & \hat{\pi}_{g,\nu-1} & \longrightarrow & \widehat{\widehat{\mathcal{T}}}^{!}_{g,\nu} & \longrightarrow & \widehat{\widehat{\mathcal{G}}}^{!}_{g,\nu-1} & \longrightarrow & 1
\end{array}$$

The map
[↪ 140-2-348-M1]

$$\text{Prediscretifications}|\text{Prediscretifications}^{+}(\pi) \longrightarrow \text{Prediscretifications}|\text{Prediscretifications}^{+}(\pi')$$

is thus identified with $\widehat{\widehat{\mathcal{T}}}^{!}_{g,\nu}/\widehat{\mathcal{T}}^{!}_{g,\nu}$, we read off the diagram that this is $\simeq \widehat{\widehat{\mathcal{G}}}^{!}_{g,\nu-1}/\widehat{\mathcal{G}}^{!+}_{g,\nu-1}$, whence bijectivity on the sets of oriented prediscretifications.

In the group $\widehat{\widehat{\mathcal{T}}}^{!}_{g,\nu} = \mathcal{T}$, we have an invariant subgroup $\hat{\pi}_{g,\nu-1} = \pi'$, and a subgroup Σ $(= | \longleftarrow \widehat{\mathcal{T}}^{!+}_{g,\nu})$ [p. 347]

[scan 349]

between π' and $\mathcal{T}$, [d1] giving[i1] a subgroup $\Sigma' \simeq \mathcal{T}(\pi')(= \widehat{\mathcal{G}}^{!+}_{g,\nu-1})$[i2] in $\mathcal{T}' = \mathcal{T}/\pi'$ $(\simeq \widehat{\widehat{\mathcal{G}}}^{!}_{g,\nu-1})$, and we know well that then

$$\mathcal{T}/\Sigma \simeq \mathcal{T}'/\Sigma',$$

and [d2] that the normalizer $\mathcal{N}$,[i3] of Σ in $\mathcal{T}$ is the inverse image of the normalizer $\mathcal{N}'$ of Σ' in $\mathcal{T}'$, so that $\mathcal{N}/\Sigma \simeq \mathcal{N}'/\Sigma'$, which proves what we wanted.

Corollary We have canonical isomorphisms

$$\Gamma_{g,\nu} \xrightarrow{\sim} \Gamma_{g,\nu-1} \xrightarrow{\sim} \cdots$$

m459

Marginal note. [m459] We also see that $\Sigma|\Sigma^{!}$ invariant in $\mathcal{T}|\widehat{\mathcal{T}}$ is equivalent to Σ' invariant in $\widehat{\widehat{\mathcal{T}}}'$

so that if $g \geq 2$, we have canonically $\Gamma_{g,\nu} \simeq \Gamma_{g,0}$, on the other hand $\Gamma_{1,\nu} \simeq \Gamma_{1,1}$ $(g = 1, \nu \geq 1)$, $\Gamma_{0,\nu} \simeq \Gamma_{0,3}$ $(\nu \geq 3)$.

N.B. The "fact" [d4] assumed is far from obvious — even that $\widehat{\widehat{\mathcal{T}}}^{!}_{g,(\nu,\nu-1)} \longrightarrow \widehat{\widehat{\mathcal{T}}}_{g,\nu-1}|\widehat{\widehat{\mathcal{M}}}_{g,\nu-1}$ is surjective, or that $\widehat{\widehat{\mathcal{T}}}_{g,(\nu,\nu-1)} \longrightarrow \widehat{\widehat{\mathcal{G}}}_{g,\nu-1}$ is injective, is far from obvious, and is perhaps altogether false !

The assumed fact amounts to a statement of the existence of a functor in the opposite direction "drilling holes", which|what in any case remains not understood.

[p. 177]

28. Change of type (g, ν) (continued) : passage to a finite covering.

Let π be a profinite group with loops[i1] of type (g, ν), anabelian as always, π' a subgroup of finite index. We know (or we|we thereby verify, by passing to the discrete case) that [d1] equipped with the[i2] traces on|under π of the loop subgroups of π, π' is a group with loops.
[d2]

The loop subgroups are also|thus the [d6] subgroups L' such that

$$\text{a)} \quad L' = \mathrm{Centr}_\pi(L') \cap \pi'.$$

$$\text{b)} \quad L = \,|\, : \mathrm{Centr}_\pi(L') \text{ is a loop subgroup in } \pi.$$

We put $d(L') = [L : L']$, and we thus have a function

$$d : I' = I(\pi') \longrightarrow \mathbb{N}^*,$$

and a map $I' \xrightarrow{\varphi} I$, such that $\forall i \in I$, we have

$$(1) \qquad \sum_{\substack{i' \in I' \\ \text{over } i}} d(i') = n \qquad (\text{where|here } n = [\pi : \pi'])$$

We will have the Hurwitz formula

$$(2) \qquad 2g' - 2 = n(2g-2) + \overbrace{\sum_{i' \in I'} (d(i') - 1)}^{n \,\mathrm{card}\, I - \mathrm{card}\, I'}$$

Scans 351–360

[scan 351]

i.e.

$$(3) \qquad 2g' - 2 + \operatorname{card} I' = n(2g - 2 + \operatorname{card} I)$$

(N.B. [d1] $(2g-2+\operatorname{card} I)$ is the negative of[i1] the Euler–Poincaré characteristic with compact supports of the curve of which $\Pi|\pi$ is the fundamental group…) ✓
m460

Marginal note. [m460] N.B. saying that we are in the anabelian case means that $-\mathrm{EP}_!$ is ≥ 1 — this condition|relation is therefore preserved by passage to a covering|to coverings. The integer $-\mathrm{EP}_!$ measures strict positivity [illeg. 1] degree of anabelianity, in some sense…

Obviously, every discretification of $\Pi|\pi$ defines one of $\Pi|\pi'$ — and the same holds for oriented discretifications, modulo a bit of cohomology [which amounts to saying, in the discrete case for example|for example)[i2] that

$$\begin{array}{ccc} H^2_!(U|\mathcal{U}, \mathbb{Z}|\mathbf{Z}) & \longrightarrow & H^2_!(U'|\mathcal{U}', \mathbb{Z}|\mathbf{Z}) \\ \wr & & \wr \\ T & & T' \end{array}$$

can be written in the form $n\theta^{-1}$, where θ is a well-determined isomorphism (the trace isomorphism) θ|of $T' \xrightarrow{\sim} T$.

It is not clear to me at first sight whether the map

$$\mathrm{Discret}(\Pi|\pi)\text{–}| \longrightarrow \mathrm{Discret}(\Pi|\pi')$$

is surjective, or injective. Injectivity (for every $\Pi|\pi'$ of finite index in $\Pi|\pi$)[i3] would mean that: two discretifications $\Pi|\pi_0, \Pi|\pi_0'$ of $\Pi|\pi$ which are commensurable, i.e. such that $\Pi|\pi_0 \cap \Pi|\pi_0'$ is of finite index in $\Pi|\pi_0$ and in $\Pi|\pi_0'$, [d2] equal[i4]

[scan 352]

[p. 178] Suppose that $\Pi|\pi'$ is an invariant subgroup in $\Pi|\pi$, put $G = \Pi|\pi'/\Pi|\pi$

Conjecture The map $\mathrm{Discret}(\Pi|\pi) \longrightarrow \mathrm{Discret}(\Pi|\pi')$ is injective, and its image consists of the discretifications $\Pi|\pi_0' \subset \Pi|\pi'$ such that $G \longrightarrow \mathrm{Aut}\,\mathrm{ext}_{\mathrm{lac}}(\Pi|\pi') \simeq \mathrm{Aut}\,\mathrm{ext}_{\mathrm{lac}}(\widehat{\Pi|\pi_0'}) \simeq \widehat{\widehat{\mathcal{T}}}(\widehat{\Pi|\pi_0'})$ factors through $\mathcal{T}(\Pi|\pi_0') = \mathrm{Autext}_{\mathrm{lac}}(\Pi|\pi_0')$ (and in fact, even through $\mathcal{T}(\Pi|\pi_0')^+$).

m461

Marginal note. [m461] In other words, $\forall g \in \Pi|\pi$, $\exists h \in \Pi|\pi'$ such that $\mathrm{int}(hg)(\Pi|\pi_0') \subset \Pi|\pi_0'$ i.e. $\Pi|\pi'|\Pi|\pi_0' \cdot \Pi|\pi_0 = \Pi|\pi$, where $\Pi|\pi_0$ is the normalizer of $\Pi|\pi_0'$ in $\Pi|\pi$.

The condition for a [d1] $\Pi|\pi_0'$ to be in the image is obviously necessary. Let us show that it is sufficient, and that the $\Pi|\pi_0^*$ giving rise to $\Pi|\pi_0'$ by $\Pi|\pi_0 \cap \Pi|\pi'$ is unique. We have an outer action of G on $\Pi|\pi_0'$, which defines the outer action on $\widehat{\Pi|\pi_0'} \simeq \Pi|\pi'$, now $\Pi|\pi$ is recovered canonically from the latter (since $\mathrm{Centre}(\widehat{\Pi|\pi'}) = 1$), and we see that it is the [d2] profinite completion[i1] of the extension $\Pi|\pi_0$ [i2] of G by $\Pi|\pi_0'$, defined by the outer[i3] action of G on $\Pi|\pi_0'$. We do indeed have a generalized discretification $\Pi|\pi_0$ of $\Pi|\pi$[i4], in the sense of just the structure of a [d3] profinite group, and it induces $\Pi|\pi_0'$ — but we must see that it is compatible with the loop structure of $\Pi|\pi$.

[scan 353]

But this is made explicit, starting from the loop structure of $\Pi|\pi'$, we take the loop subgroups L'^{i1} of $\Pi|\pi'$, and their Centralizers in $\Pi|\pi$. Let us do the same for $\Pi|\pi_0 \supset | > \Pi|\pi'_0$, we should find a loop structure on $\Pi|\pi_0$, giving rise to the sames d_i. I have the feeling that this should not be too nasty to prove — it would be as if we already knew that every "torsion-free"^{i2} extension of a finite group by a group with loops is (in the canonical way) a group with loops…

Corollary In any case, the map $\mathrm{Discret}(\Pi|\pi) \longrightarrow \mathrm{Discret}(\Pi|\pi')$ is injective.

N.B. It should not always be bijective, for there must be an outer|outer^{i3} action of a G on a $\widehat{\Pi|\pi'_0}$ i.e. homomorphisms $G \longrightarrow \widehat{\widehat{\mathcal{T}}}(\widehat{\Pi|\pi'_0})$, which do not factor|factor through $\mathcal{T}(\Pi|\pi'_0)$, and which nevertheless is as good|good from the profinite group point of view as that|those coming from a $\Pi|\pi$ and a subgroup

[p. 179]

invariant $\Pi|\pi'$. In fact, let us start from such a discrete situation $\Pi|\pi_0 \supset | > \Pi|\pi'_0$, whence $G = \Pi|\pi_0/\Pi|\pi'_0$ and $G \longrightarrow \mathrm{Autext}_{\mathrm{lac}}(\Pi|\pi'_0) = \mathcal{T}(\Pi|\pi'_0) \subset \widehat{\mathcal{T}}|\widehat{\widehat{\mathcal{T}}}(\widehat{\Pi|\pi'_0})$, and conjugate G by an element γ^{i1} of $\widehat{\widehat{\mathcal{T}}}(\Pi|\pi'_0)$, so as to find $G \longrightarrow \widehat{\mathcal{T}}(\widehat{\Pi|\pi'_0})$ which does ^{d2} not factor through $\mathcal{T}(\Pi|\pi'_0)$. We find an extension $\widehat{\Pi|\pi}|\Pi|\pi^{\natural|\sharp}{}^{i2}$ of G by $\widehat{\Pi|\pi'_0}$, isomorphic to $\widehat{\Pi|\pi_0}$ (as an extension of G by

$\widehat{\Pi|\pi_0}'$), hence the loop structure of $\widehat{\Pi|\pi_0}'$ defines one on $\Pi|\pi^{\natural|\sharp}$ d3 (so as to be[i3] induced by the latter), but nevertheless the chosen discretification $\Pi|\pi_0$[i4] of $\widehat{\Pi|\pi_0}$ is not induced by one of $\Pi|\pi$. To

∗ Carry out the construction, it suffices to find an element $\gamma \in \widehat{\widehat{\mathcal{T}}}(\Pi|\pi_0')$ d4 such that $\mathrm{int}(\gamma).G\not\subset \mid \not\in\mathcal{T}$,[i5] d5

[A large part of the canceled passage is enclosed by a frame (left, bottom and right sides) and crossed out with four long slanting strokes. After the inclusion $\gamma^{-1}.\Pi|\pi_0' \subset \widehat{\Pi|\pi_0}'$ on the last line, stroke curved into a hook, directed toward the following inclusion.]

i.e. such that G d9 does not stabilize $\gamma^{-1}(\Pi|\pi_0') \subset \widehat{\Pi|\pi_0}'$[i9]
Such a γ always exists....

[scan 355]

Of course, there is no reason, [d1] for two discretifications $\Pi|\pi'_0|\Pi|\pi_0, \Pi|\pi_1$ of $\Pi|\pi$, that if $\Pi|\pi_0, \Pi|\pi_1$ are $\Pi|\pi$-conjugate (i.e. define [d2] the same[i1] strict prediscretification|prediscretification[d3] of $\Pi|\pi$), the same should hold for $\Pi|\pi'_0$ and $\Pi|\pi'_1$ under the inner action of $\Pi|\pi'$. (It would be necessary for $\Pi|\pi_0, \Pi|\pi_1$ to be conjugate by $\Pi|\pi'$, and not just by $\Pi|\pi$). On the other hand, I presume that if $\Pi|\pi_0, \Pi|\pi_1$ are "adherent" to one another in the space of discretifications|discretifications of $\Pi|\pi$, i.e. if they define the same prediscretification, the same holds for $\Pi|\pi'_0, \Pi|\pi'_1$, and that the map

$$\text{Prédiscrt}^+(\Pi|\pi) \longrightarrow \text{Prédiscrt}^+(\Pi|\pi') \tag{4}$$

which we obtain in this way, is again bijective, and that it in turn passes to the quotient, to define a bijective map

$$\text{Préarith} \,|\, \text{Préarithm}(\Pi|\pi) \longrightarrow \text{Préarith} \,|\, \text{Préarithm}(\Pi|\pi'), \tag{5}$$

and that if Σ, Σ' correspond to one another under the latter, that we have a canonical isomorphism

$$\mathbb{\Gamma}|\Gamma_\Sigma \longrightarrow \mathbb{\Gamma}|\Gamma_{\Sigma'}, \tag{6}$$

compatible,

[p. 180]

with the actions of these groups on the set P_Σ of prediscretifications of $\Pi|\pi$ compatible with Σ, and the set $P_{\Sigma'}$[i1] of prediscretifications of $\Pi|\pi'$ compatible with Σ' (which are resp. left

torsors under $\mathbb{\Gamma}|\Gamma_{\Sigma}, \mathbb{\Gamma}|\Gamma_{\Sigma'}$). At the same time, we will find therefore[i2] that Σ is unique for $\Pi|\pi$ i.e. invariant under $\widehat{\widehat{\mathcal{T}}}(\Pi|\pi)$, iff Σ' is unique in $\Pi|\pi'$ i.e. invariant under $\widehat{\widehat{\mathcal{T}}}(\Pi|\pi')$.

In any case, the fundamental conjecture which interprets the $\mathbb{\Gamma}|\Gamma_{g,\nu|v}$ as $\mathbb{\Gamma}|\Gamma_0 = \mathrm{Gal}(\overline{\mathbb{Q}}_0/\mathbb{Q})$ would have|will have at least as a consequence that the map $\mathrm{Discr}^+(\Pi|\pi)-| \longrightarrow \mathrm{Discr}^+(\Pi|\pi')$ passes to the quotient in[i3] two ways, to give a commutative diagram

$$\begin{array}{ccc}
\mathrm{Discr}^+(\Pi|\pi) & \longrightarrow & \mathrm{Discr}^+(\Pi|\pi') \\
\downarrow & & \downarrow \\
P|p = \mathrm{Prédiscr}^+(\Pi|\pi) & \longrightarrow & P|p' = \mathrm{Prédiscr}^+(\Pi|\pi') \\
\downarrow & & \downarrow \\
A = \mathrm{Arithm}(\Pi|\pi) & \longrightarrow & A' = \mathrm{Arithm}(\Pi|\pi')
\end{array}$$

and that the [d1] lower square is cartesian (without prejudging the injectivity or the bijectivity of the map $A \longrightarrow A'$). So it would be necessary

that [d1] if $\Pi|\pi_0, \Pi|\pi_1$ are two discretifications (oriented)[i1] of $\Pi|\pi$, which define the same prediscretification (oriented), then the same holds for their traces on $\Pi|\pi'$,[i2] $\Pi|\pi'_0$ and $\Pi|\pi'_1$, with respect to $\Pi|\pi'$. But already if $\Pi|\pi_0$ and $\Pi|\pi_1$ are $\Pi|\pi$-conjugate (i.e. define same discretification (oriented, strict)), this is not so clear — [d2] but yes, for we will have $\Pi|\pi = \Pi|\pi' \cdot \Pi|\pi_0$ hence if $\Pi|\pi_1 = \mathrm{int}(u)\Pi|\pi_0$ writing $u = u'u_0$ with $u' \in \Pi|\pi'$, $u_0 \in \Pi|\pi_0$, we will have

$$\Pi|\pi_1 = \mathrm{int}(u')\,\mathrm{int}(u_0)\Pi|\pi_0 = \mathrm{int}(u')\Pi|\pi_0,$$

hence $\Pi|\pi'_1 = \mathrm{int}(u')\Pi|\pi'_0$ hence $\Pi|\pi'_0$ and $\Pi|\pi'_1$ are conjugate.

Let us try to proceed in the same way in the general case of a $u \in \mathcal{C}|\widehat{\mathcal{G}(\Pi|\pi_0)}^+$, such that $\Pi|\pi_1 = u(\Pi|\pi_0)$,[i3] writing if possible $u = u'u_0$, with $u' \in \mathcal{C}|\widehat{\mathcal{G}(\Pi|\pi_0, \Pi|\pi'_0)}^+$, and $u_0 \in \mathcal{C}|\mathcal{G}(\Pi|\pi_0)^+$, where we define $\mathcal{C}|\mathcal{G}(\Pi|\pi_0, \Pi|\pi'_0)^+$ as the group of i-automorphisms|l-automorphisms direct|discrete[i4] of $\Pi|\pi_0$ which stabilize $\Pi|\pi'_0$, and $\widehat{\mathcal{C}|\mathcal{G}}(\Pi|\pi_0, \Pi|\pi'_0)^+$ is its profinite compactification. We would then have $\Pi|\pi_1 = u'(u_0(\Pi|\pi_0)) = \dot{u}'(\Pi|\pi_0)$, where [d3] $\dot{u}'$ denotes the image of u' in $\mathcal{T}|\widehat{\mathcal{C}(\Pi|\pi'_0)}$. In any case, there is no problem if $\Pi|\pi'$ is a [d5] characteristic subgroup of $\Pi|\pi$, for then we have a homomorphism

[p. 181] discrete $\mathcal{C}|\mathcal{G}(\Pi|\pi_0) \longrightarrow \mathcal{C}|\mathcal{G}(\Pi|\pi_0')$, defining the|the $\widehat{\mathcal{C}|\mathcal{G}}(\widehat{\Pi|\pi_0}) \longrightarrow \widehat{\mathcal{C}|\mathcal{G}}(\widehat{\Pi|\pi_0'})$. Since the open characteristic subgroups of $\Pi|\pi$ are cofinal, we are reduced (for the questions of factorizability of $D(\Pi|\pi) \longrightarrow D(\Pi|\pi')$ into $P(\Pi|\pi) \longrightarrow P(\Pi|\pi')$ and $A(\Pi|\pi) \longrightarrow A(\Pi|\pi')$[i1] and of bijectivity of the maps $P(\Pi|\pi) \longrightarrow P(\Pi|\pi')$ and $A(\Pi|\pi) \longrightarrow A(\Pi|\pi')$) we are reduced to the case where $\Pi|\pi'$ is a characteristic subgroup. We have indeed|seen then[i2] [d1] factorizability of $D(\Pi|\pi) \longrightarrow D(\Pi|\pi')$ into $P(\Pi|\pi) \longrightarrow P(\Pi|\pi')$, we want[i3] to show|let us show that this map is injective ... This[i4] [d2] ⓐ[i5] means that the inverse image in $\widehat{\widehat{\mathcal{C}|\mathcal{G}}}(\widehat{\Pi|\pi_0})$ of $\widehat{\mathcal{C}|\mathcal{G}}(\widehat{\Pi|\pi_0'})^+$ is $\widehat{\mathcal{C}|\mathcal{G}}(\widehat{\Pi|\pi_0})^+$, the surjectivity ⓑ[i6] means that every element of $\widehat{\widehat{\mathcal{C}|\mathcal{G}}}(\widehat{\Pi|\pi_0'})$ is congruent modulo $\mathcal{C}|\mathcal{G}(\widehat{\Pi|\pi_0'})^+$ to an element of the image of $\widehat{\widehat{\mathcal{C}|\mathcal{G}}}(\Pi|\pi_0)$. The factorizability into $A(\Pi|\pi) \longrightarrow A(\Pi|\pi')$ means that by ⓒ[i7] the preceding map [d3] $\widehat{\widehat{\mathcal{C}|\mathcal{G}}}(\Pi|\pi_0) \hookrightarrow \widehat{\widehat{\mathcal{C}|\mathcal{G}}}(\Pi|\pi_0')$, (N.B. it is immediate that it is injective) [d4] sends[i8]

$$M(\Pi|\pi_0) = \mathrm{Norm}_{\widehat{\widehat{\mathcal{C}}}|\widehat{\mathcal{C}}(\Pi|\pi_0)}(\widehat{\mathcal{C}|\mathcal{G}}^+(\Pi|\pi_0))$$

into $M(\Pi|\pi_0')$, the injectivity of $A(\Pi|\pi) \longrightarrow A(\Pi|\pi')$ that

[p. 182]

Perhaps the properties a) b) c) are completely false – yet a) (which corresponds to the injectivity of $P(\Pi|\pi) \longrightarrow P(\Pi|\pi')$) seems fairly plausible. Property b) (which would express the surjectivity of $P(\Pi|\pi) \longrightarrow P(\Pi|\pi')$) is much more problematic, even doubtful. The trouble is that the group $\widehat{\widehat{\mathcal{C}|\mathcal{G}}}(\Pi|\pi_0)$ can be "much smaller" than $\widehat{\widehat{\mathcal{C}|\mathcal{G}}}(\Pi|\pi_0')$, we realize this by passing to the quotient by the subgroup $\widehat{\Pi|\pi_0}' = \Pi|\pi'$ (contained in the smallest of the groups in (7), and normal in the largest), we find on the second line the groups $\widehat{\mathcal{T}}^{+}(\Pi|\pi_0')$, d1 $\mathcal{N}|N(\Pi|\pi_0')$ and $\widehat{\widehat{\mathcal{T}}}(\Pi|\pi_0')$, on the first extensions of the corresponding|corresponding groups for $\Pi|\pi_0$ ($\widehat{\mathcal{T}}^{+}(\Pi|\pi_0)$, $\mathcal{N}|N(\Pi|\pi_0)$ and $\widehat{\widehat{\mathcal{T}}}(\Pi|\pi_0)$) by the finite group[i1] $G = \Pi|\pi_0/\Pi|\pi_0' \simeq \Pi|\pi/\Pi|\pi'$, d2 denoted|denoted by $\sim$'s, so that .|–

$$(8)\qquad \begin{array}{ccccccc} G & \subset & \widetilde{\widehat{\mathcal{T}}}^{+:}(\pi_0) & \subset & \widetilde{\mathcal{N}}(\pi_0) & \subset & \widetilde{\widehat{\widehat{\mathcal{T}}}}(\pi_0) \\ & \searrow & \Big\uparrow & & \Big[\Big\downarrow ?\Big] & & \Big\downarrow \\ & & \widehat{\mathcal{T}}^{+}(\pi_0') & \subset & \mathcal{N}(\pi_0') & \subset & \widehat{\widehat{\mathcal{T}}}(\pi_0') \end{array}$$

[p. 183] on the other hand we would absolutely need c) in order at least to define $A(\pi) \longrightarrow |-A(\pi')$ and (if Σ, Σ' correspond) $\Gamma_\Sigma \longrightarrow |-\Gamma_{\Sigma'}$, in the case $\pi_a'|\pi_0'$ [d1]characteristic[i1] in π (and in all cases if in addition we admit a), which seems rather plausible, and gives the injectivities required. But one does wonder why an element of [d2] $\widehat{\widehat{\mathcal{T}}}(\pi_0')$ simply because it [d3]is in[i2] the [d4]normalizer R of G[i3] [d5]in[i4] $\widehat{\widehat{\mathcal{T}}}(\pi_0')$, hence also R,[i5] and it normalizes $R \cap \widehat{\mathcal{T}}^{+}(\pi_0')$, should also normalize $\widehat{\mathcal{T}}^{+}(\pi_0')$ itself ! It is true that we made draconian hypotheses at the outset (starting from a characteristic subgroup π_0' of π_0) which must surely be reflected in special properties of $G \subset \mathcal{T}^{+}(\pi_0')$. Perhaps in the end the trick of reducing to characteristic subgroups to examine [p. 361]

[scan 363]

the situation is itself not so clever. To see more clearly, we could already try to understand the case where (without assuming π' characteristic) we assume π' of index 2 in π, hence invariant and $G \simeq \mathbb{Z}/2$, or else we take [d1] the kernel of the canonical homomorphism $\pi \longrightarrow (\pi_{\mathrm{ab}})_2$ ($\simeq (\mathbb{Z}/2\mathbb{Z})^{2g}$ if $\nu = 0$, $\simeq (\mathbb{Z}/2\mathbb{Z})^{2g+|-\nu-1}$ if $\nu \geq 1$), taking for example $\pi = \widehat{\Pi}_{0,3}$ — situation of the Fermat curve $x^2 + y^2 + z^2 = 0$ (octahedral covering of $\mathbb{P}^1_{\mathbb{Q}} \setminus \{0, 1, \infty\}$ …)

But let us provisionally admit the [d3]hypotheses[i1] of injectivity (relatively innocuous), plus the condition c), not innocuous at all — whence, if Σ and Σ' correspond, an injective homomorphism

$$(9) \qquad \Gamma_\Sigma \hookrightarrow \Gamma_{\Sigma'},$$

and let us see what we could get from it. even admitting, provisionally (to see) that (9) is an isomorphism — [d4] that is to say the full force of the main conjecture $\Gamma_0 \simeq \Gamma_{g,\nu}$. [p. 362]

[p. 184]

Let|Let π be a profinite group with loops[i1] of type (g, ν), π' of type (g', ν'). Let us call a "correspondence" between π and π' a [d1] pair consisting of a profinite $G|\pi''$ with loops[i2] [d2], and of homomorphisms with loops[i3] $G|\pi'' \xrightarrow{p} \pi$, $G|\pi'' \xrightarrow{q} \pi'$ which are therefore each|each composed|composed of a "plugging holes" morphism, and of an [d3] isomorphism onto a subgroup|subgroup of finite index. Let|Let $J_p|I''_p$, $J_q|I''_q \in J|I'' = I(\pi'')$ be the sub[i4]sets of $J|I''$ which correspond to the "holes plugged by p" resp. by q, we assume if necessary[i5] $J_p|I''_p \cap J_q|I''_q = \emptyset$ (otherwise one could factor through the same quotient $\tilde{\pi}''$ of π''). In other words if $\overline{J}_p|\overline{I}''_p$, $\overline{J}_q|\overline{I}''_q$ are the complements of $J_p|I''_p$, $J_q|I''_q$ in $J|I''$ (so that we have : $\overline{J}_p|\overline{I}''_p \to I = I(\pi)$, $\overline{J}_q|\overline{I}''_q \to I' = I(\pi')$) we have

$$\overline{J}_p|\overline{I}''_p \cup \overline{J}_q|\overline{I}''_q = J|I''.$$

[d4]

We are now going to suppose π equipped with a $\Sigma \in A(\pi)$[i6], π' equipped with a $\Sigma' \in A(\pi')$, we shall call an "arithmetic correspondence" between π and π' a quadruple $(G|\pi'', p, q, \Sigma_G|\Sigma'')$, where $(G|\pi'', p, q)$ are as above, and $\Sigma^a_G|\Sigma_G \in A(G)$, such that we have $\Sigma_G|\Sigma_a = p^*(\Sigma) = q^*(\Sigma')$. $P_{\Sigma'}$, $P_{\Sigma_G|\Sigma_a}$ are resp. the torsors under Γ_Σ, $\Gamma_{\Sigma'}$, $\Gamma_{\Sigma''}$ that we know, we have two diagrams|diagram of isomorphisms of torsors

, whence by composition an isomorphism|homomorphism of [d1]

$$(P_\Sigma, \Gamma_\Sigma) \xrightarrow{\sim} (P_{\Sigma'}, \Gamma_{\Sigma'})$$

We call "arithmetically outer isomorphisms" of (π, Σ) with (π', Σ'),[i1] any isomorphism of torsors that we can obtain in this way. Two correspondences are said to be equivalent [d2] from the point of view[i2] [d3] arithmetically outer, if they define the same|= arithmetically outer isomorphism. The composition is defined by composition of the actions on $(P_\Sigma, \Gamma_\Sigma)$ — we see that this comes from a correspondence. We find therefore a groupoid, which we check without difficulty is connected. I say that[i3] The automorphisms of (π, Σ) "are" the automorphisms of $(P_\Sigma, \Gamma_\Sigma)$ defined by elements of Γ_Σ. [d4] This is easy…
m463

Marginal note. [m463] We shall call it the groupoid of "outer arithmetic curves".

[p. 186]

29 Critique of the preceding approach.

The approach of the|of the preceding § seems frankly|in the end very brutal. I even have doubts whether the|the [d1] conjecture in|on the properties of the "plugging holes" functor is true as it stands. It is true that for a profinite group [d2] with[i1] loops π, if we fix $i \in I(\pi)$, we have a canonical homomorphism

$$\widehat{\widehat{\mathcal{F}}}(\pi, i) = \underset{\substack{\text{stabilizer} \\ \text{of } i \text{ in } \widehat{\widehat{\mathcal{F}}}(\pi)}}{\underline{\widehat{\widehat{\mathcal{F}}}(\pi)_i}} \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi'), \tag{1}$$

but it is problematic whether this is an isomorphism — and even whether it is injective, or whether it is surjective. But, choosing a discretification $\pi_0 \subset \pi$, whence ditto π_0' for π', the preceding homomorphism does indeed induce an isomorphism

$$\mathcal{T}(\pi_0)_i \simeq \mathcal{G}(\pi_0') \tag{1}$$

whence

$$\widehat{\mathcal{T}}(\pi_0) \xrightarrow{\sim} \widehat{\mathcal{G}}(\pi_0') \tag{3}$$

and consequently, the exact sequence $\hat{\pi}'_0 \longrightarrow \widehat{\mathcal{G}}(\pi'_0) \longrightarrow \widehat{\mathcal{T}}(\pi'_0) \longrightarrow 1$ gives

$$1 \longrightarrow \hat{\pi}'_0 \longrightarrow \widehat{\mathcal{T}}(\pi_0) \longrightarrow \widehat{\mathcal{T}}(\pi'_0) \longrightarrow 1 \tag{4}$$

and consequently we find an injective homomorphism

$$\begin{array}{ccc} \hat{\pi}'_0 & & \widehat{\widehat{\mathcal{T}}}(\pi_0)_i \\ \| \hookrightarrow | \leftrightarrow \widehat{\mathcal{T}}(\pi_0)_i & \hookrightarrow & \| \\ \pi' & & \widehat{\widehat{\mathcal{T}}}(\pi) \end{array}$$

hence a homomorphism

$$i_{\pi_0} : \quad \pi' \longrightarrow \widehat{\widehat{\mathcal{T}}}(\pi)_i \tag{5}$$

for which the|the composite with (1) is the canonical injection $\pi' \hookrightarrow \widehat{\widehat{\mathcal{G}}}(\pi')$. Replacing the discretification π_0 [i2] by another, π_1, we find a priori another homomorphism $i_{\pi_1} : \pi' \longrightarrow \widehat{\widehat{\mathcal{T}}}(\pi)_i$. We may assume $\pi_1 = u(\pi_0)$, $u \in \widehat{\widehat{\mathcal{T}}}(\pi)_i$;

[scan 368]

and by transport of structure we find

$$i_{\pi_1} = i_{u(\pi_0)} = \mathrm{int}(u) \circ i_{\pi_0} \circ u_{\pi'}^{-1}$$

where $u_{\pi'}$ is the automorphism of π' defined by u via (1). To say that i_{π_0} is independent of the choice of the discretification π_0, also amounts to saying that its image in $\widehat{\widehat{\mathcal{T}}}(\pi)_i$ is an invariant subgroup — and then the action of $\widehat{\widehat{\mathcal{T}}}(\pi)_i$ on [d1] the invariant subgroup $i_{\pi_0}(\pi) = i(\pi)$ [d2] via inner automorphisms, is none other than that defined by (1). In this case, we find by passage to the quotient a homomorphism

$$\widehat{\widehat{\mathcal{T}}}(\pi)_i/\pi' \longrightarrow \widehat{\widehat{\mathcal{T}}}(\pi') \tag{6}$$

whose injectivity resp. surjectivity would be equivalent to that of (1). But it is not at all obvious that it is always so.

If it were not so, it [d3] would be necessary to look at the subgroup of $\widehat{\widehat{\mathcal{T}}}(\pi)_i$ formed of the $\gamma \in \widehat{\widehat{\mathcal{T}}}(\pi)_i$ which[i1] [d4] normalize the [d5] subgroup $i_{\pi_0}(\pi')$, and such that the action induced on

$i_{\pi_0}(\pi')$ corresponds to that given by the action (1) of $\widehat{\widehat{\mathcal{T}}}(\pi)$ on π'. This subgroup $H_{\pi_0,i}$ (which contains $\widehat{\mathcal{T}}(\pi_0)_i$) [d6i2] therefore depends a priori on the chosen discretification. Replacing π_0 by $u(\pi_0)$ (where [d7] $u \in \widehat{\widehat{\mathcal{T}}}(\pi_0|\pi)_i$) replaces it by $\mathrm{int}(u).H$ — hence H

[p. 187]

at least does not change, if we vary π_0 within their|a class of prediscretification.

We can do more symmetric things, by considering for every $i \in I$ the corresponding quotient π'_i of π, whence, for a chosen discretification π_0, homomorphisms

$$i_{\pi_0,i} : \pi'_i \longrightarrow \widehat{\widehat{\mathcal{T}}}(\pi)_i \subset \widehat{\widehat{\mathcal{T}}}(\pi)$$

and we shall define $H_{\pi_0} \subset \widehat{\widehat{\mathcal{T}}}(\pi)$ as the subgroup of the $\gamma \in \widehat{\widehat{\mathcal{T}}}(\pi)$ which "permute the [d1]$i_{\pi_0,i}$[i1] among themselves" in an evident sense. Thus we have

$$H_{\pi_0} \cap \widehat{\widehat{\mathcal{T}}}(\pi)_i = H_{\pi_0,i} \tag{7}$$

and

$$H \supset \widehat{\mathcal{T}}(\pi_0) \tag{8}$$

The point I have in view, is that the subgroup of $\widehat{\widehat{\mathcal{T}}}(\pi_0)$ image of $\pi_1(M_{g,\nu})$, must not only normalize $\widehat{\mathcal{T}}(\pi_0)^+$, but moreover be contained in this H. This is a condition I have encountered

by the back door, [d2]thanks to[i2] the hypothesis (may be very hasty) that (1) is an isomorphism, which implied (tacitly) that we had $H = \widehat{\widehat{\mathcal{T}}}(\pi_0)$ in its entirety. It is possible that $\widehat{\widehat{\mathcal{T}}}(\pi_0)$ is a group so enormous|unreasonable and pathological, that there will never be any question of saying reasonable (and true)[i3] things about [d3] this whole group (such as the bijectivity of (1), for example

and that we are obliged to work with smaller subgroups, which remain close to the discrete (with all the same some additional "arithmetic" aspects, due to the $\Gamma_0 = \mathrm{Gal}(\overline{\mathbb{Q}}_0/\mathbb{Q})$!). In fact, there is (for $I = I(\pi) \neq \emptyset$ i.e. $\nu \neq 0$)[i1] in the group $\widehat{\mathcal{T}}(\pi_0)$ a simplicial[i2] structure of successive extensions, which is going to be respected by the outer action of the Galois group, and which we should take into account. It is part of the "structure at|: ∞" in the π_1 of the [d1] modular multiplicities $M_{g,\nu}$, which even for $\nu = 0$ is probably nontrivial, and it may be necessary to take it into account, to manage to put our finger on $\Gamma_{\mathbb{Q}}$.

Without trying to give from the outset an a priori description of $\Gamma_{\mathbb{Q}}$ "in the $\widehat{\widehat{\mathcal{T}}}_{g,\nu}$", we are going to proceed in a more inductive way, starting from the presence of $\Gamma_{\mathbb{Q}}$ (for arithmetico-geometric reasons), and trying to bring out properties of this presence, perhaps strong enough to end up giving a purely algebraic characterization.

Scans 371–380

[scan 371]

[p. 188]

Let us recall that, via the choice of $U_{g,\nu}$ (differentiable), we had been able to construct by transcendental means a $\widetilde{M}_{g,\nu\mathbb{C}}$and a $\widetilde{\mathcal{U}}_{g,\nu\mathbb{C}}|\mathcal{U}_{g,\nu\mathbb{C}} = \widetilde{M}_{g,\nu+1\,\mathbb{C}}|M_{g,\nu+1\,\mathbb{C}}$[i1], hence a $\widetilde{M}_{g,\nu\mathbb{Q}}$, [d1]and a[i2] $\widetilde{\mathcal{U}}_{g,\nu\mathbb{Q}}$, hence a $\pi_1(\mathcal{U}_{g,\nu,\mathbb{Q}})$, with a filtration in three steps, whose factors are respectively canonically isomorphic to

$$\hat{\pi}_{g,\nu}, \quad \widehat{\mathcal{T}(\pi_{g,\nu})}^{+}, \quad \Gamma_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}_0/\mathbb{Q}) \tag{9}$$

the group maps (we presume injectively) into $\widehat{\widehat{\mathcal{G}}}(\pi_{g,\nu})$, [d2] inducing an isomorphism between its subgroup $\pi_1(\mathcal{U}_{g,\nu\overline{\mathbb{Q}}_0})$ with $\widehat{\mathcal{G}}(\pi_{g,\nu})$, let us denote its image by $M_{g,\nu}$. So it is a subgroup closed[i3]

$$\widehat{\mathcal{G}}_{g,\nu} \subset M_{g,\nu} \subset \widehat{\widehat{\mathcal{G}}}_{g,\nu} \tag{10}$$

and $\widehat{\mathcal{G}}^{+}_{g,\nu}$ is normal in $M_{g,\nu}$(but not $\widehat{\mathcal{G}}_{g,\nu}$!)[i4]. The datum [d3]of such an[i5] $M_{g,\nu}$ is equivalent to that of an $N_{g,\nu}$

$$\widehat{\mathcal{T}}_{g,\nu} \subset N_{g,\nu} \subset \widehat{\widehat{\mathcal{T}}}_{g,\nu}, \tag{11}$$

with $\widehat{\mathcal{T}}^{+}_{g,\nu}$ normal in $N_{g,\nu}$.

We set

$$\Gamma_{g,\nu} = N_{g,\nu}/\widehat{\mathcal{T}}^{+}_{g,\nu} \simeq M_{g,\nu}/\widehat{\mathcal{G}}^{+}_{g,\nu}. \tag{12}$$

m464

Marginal note. [m464] N.B. In $\Gamma_{g,\nu}$ we have a canonical element of order 2 $\tau_{g,\nu}$, corresponding to the elements of $\widehat{\mathcal{T}}_{g,\nu} - |\searrow \widehat{\mathcal{T}}^{+}_{g,\nu} = \widehat{\mathcal{T}}^{-}_{g,\nu}$.

We have a surjective homomorphism

$$\Gamma_{\mathbb{Q}} \longrightarrow \Gamma_{g,\nu} \tag{13}$$

which we presume is bijective — i.e. that the $\Gamma_{g,\nu}$ are canonically isomorphic to one another. 370

Let π_0 now be a discrete group with loops of type g, ν, then we define subgroups M_{π_0}, N_{π_0}

$$\widehat{\mathcal{G}}(\pi_0) \subset M_{\pi_0} \subset \widehat{\widehat{\mathcal{G}}}(\pi_0) \tag{14}$$

$$\widehat{\widehat{\mathcal{T}}}(\pi_0) \subset N_{\pi_0} = M(\pi_0)/\hat{\pi}_0 \subset \widehat{\widehat{\mathcal{T}}}(\pi_0) \tag{15}$$

$\Gamma_{\pi_0} = M_{\pi_0}/\widehat{\mathcal{G}}(\pi_0)$

$\leftrightarrow ?\ \widehat{\mathcal{T}}$

using an isomorphism $\pi_0 \xrightarrow{\sim} \pi_{g,\nu}$ and proceeding by transport of structure — the result does not depend on it. More generally, let us start with a pair (π, α) of a profinite group π, equipped with a prediscretification α, which we can therefore interpret as a class of isomorphisms $\hat{\pi}_{g,\nu} \longrightarrow \pi$, defined|defined modulo composition on the right by a $u \in \widehat{\mathcal{G}}_{g,\nu}$. Then by transport of structure we deduce from it groups M_α, N_α [i5]

$$\widehat{\mathcal{G}}_\alpha \subset M_\alpha \subset \widehat{\widehat{\mathcal{G}}}(\pi) \tag{16}$$

$$\widehat{\mathcal{T}}_\alpha \subset \underset{\substack{\| \\ M_\alpha/\pi}}{N_\alpha} \subset \widehat{\widehat{\mathcal{T}}(\pi)} \tag{17}$$

$\widehat{\widehat{\mathcal{T}}}$?

with $\widehat{\mathcal{G}}(\pi)^+$ normal in M_α i.e. $\widehat{\mathcal{T}}^+(\pi)$ normal in N_α. We set

$$\Gamma_\alpha = M_\alpha/\widehat{\mathcal{G}}^+_\alpha \simeq N_\alpha/\widehat{\mathcal{T}}^+_\alpha \tag{18}$$

We have a canonical element [d8]

$$\tau_\alpha \in \Gamma_\alpha, \qquad \tau_\alpha^2 = 1, \quad \tau_\alpha \neq 1 \tag{19}$$

[scan 373]

[p. 189]

Let π now be a profinite group with loops of type (g,ν). We call an arithmetization of π the datum of an element of

$$\begin{aligned} A(\pi) &= \underline{\mathrm{Isom}}_{\mathrm{lac}}(\hat{\pi}_{g,\nu},\pi)/M_{g,\nu} \\ &\simeq \underline{\mathrm{Isomext}}_{\mathrm{lac}}(\hat{\pi}_{g,\nu},\pi)/N_{g,\nu} \end{aligned} \tag{20}$$

Let $P(\pi)$ be the set of prediscretifications oriented[i1] of π

$$\begin{aligned} P(\pi) &= \underline{\mathrm{Isom}}_{\mathrm{lac}}(\hat{\pi}_{g,\nu},\pi)/\widehat{\mathcal{G}}^+_{g,\nu} \\ &\simeq \mathrm{Isomext}_{\mathrm{lac}}(\hat{\pi}_{g,\nu},\pi)/\widehat{\mathcal{T}}^+_{g,\nu} \end{aligned} \tag{21}$$

then $\Gamma_{g,\nu}$ operates freely on the right[i2] on $P(\pi)$, and

$$A(\pi) \simeq P(\pi)/\Gamma_{g,\nu} \tag{22}$$

— $P(\pi)$ is a relative torsor over $A(\pi)$, with group $\Gamma_{g,\nu}$. For $a \in A(\pi)$, let M_a be the subgroup of $\widehat{\widehat{\mathcal{G}}}(\pi)$ of automorphisms of (π, a), it operates on the $\Gamma_{g,\nu}$-torsor P_a of oriented discretifications of π over a. For [d1] $\alpha \in P_a$, let $\widehat{\mathcal{G}}_\alpha^{*|\dagger} \subset \widehat{\widehat{\mathcal{G}}}(\pi)$, then $\widehat{\mathcal{G}}_\alpha^{+}$[i3] [d3] does not depend on α (we shall denote it|in view of the notation ([illeg. 1])![?! $\widehat{\mathcal{G}}_a$), it is also the kernel of the operation of M_a on P_a. We have [m470]

Marginal note. [m470] but. Careful $\widehat{\mathcal{G}}_\alpha^{*|\dagger}$ depends on α i.e. $\tau_\alpha \in \Gamma_a$ depends on α

$$\widehat{\mathcal{G}}_a^{+} \subset M_a \subset \widehat{\widehat{\mathcal{G}}}(\pi) \tag{23}$$

hence also 372

[scan 375]

[p. 190]

To give oneself an object of this category is essentially the = thing (up to unique isomorphism) as to give oneself a universal covering $\widetilde{M}_{g,\nu\mathbb{Q}}$[i1] of $M_{g,\nu\overline{\mathbb{Q}}}$[i2] — or a torsor under $N_{g,\nu}$; we then consider the family of curves of type g, ν over $\widetilde{M}_{g,\nu\mathbb{Q}}|M_{g,\nu\mathbb{Q}}$

$$\mathcal{U}_{g,\nu} \times_{M_{g,\nu}} \widetilde{M}_{g,\nu\mathbb{Q}} = \mathcal{U}_{g,\nu}(\widetilde{M}_{g,\nu\mathbb{Q}}) \tag{28}$$

as being "the" algebraic curve whose π_1 outer[i3] (which is therefore the π_1 of this scheme...) is the given outer group with loops.

If we took the arithmetized groups with loops, not outer, we would have again[i4] a connected groupoid with "origin" $(\hat{\pi}_{g,\nu}, a_{g,\nu})$, with a group of automorphisms which is $M_{g,\nu} \simeq \pi_1(\mathcal{U}_{g,\nu\mathbb{Q}})$[i5]. The datum of an object of this category [d1] amounts to[i6] the datum of a universal covering (not only of $M_{g,\nu\mathbb{Q}}$, but) of $\mathcal{U}_{g,\nu\mathbb{Q}}$, i.e. $\widetilde{\mathcal{U}}_{g,\nu\mathbb{Q}}$, which indeed makes it possible to serve as a reference universal covering

[scan 376]

for the relative curve (28), allowing one then to specify its fundamental group as a genuine group with loops (not just an outer group).

We can finally also look at the category of profinite groups with loops arithmetized, where we take as morphisms the arithmetically outer isomorphisms.

We again find a connected groupoid with marked origin $(\pi_{g,\nu}, a_{g,\nu})$, whose group of automorphisms is now $\Gamma_{g,\nu}$. Now the groups $\hat{\pi}_0$ (π_0 a discrete group with loops of type g, ν) are canonically isomorphic to one another. The category is (conjecturally, assuming $\Gamma_{\mathbb{Q}} \to \Gamma_{g,\nu}$ an isomorphism) equivalent to that of universal coverings of Spec $\mathbb{Q}$, i.e. to that of algebraic closures of $\mathbb{Q}$, the origin element corresponding to $\overline{\mathbb{Q}}_0$. 375

[scan 377]

[p. 191]

When we give ourselves a π with arithmetization a, then there [d1] corresponds to it therefore canonically an algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$. The $\Gamma_{\mathbb{Q}}$ [i1] torsor of isomorphisms $\mathrm{Isom}(\overline{\mathbb{Q}}_0, \overline{\mathbb{Q}})$, i.e. of embeddings $\overline{\mathbb{Q}} \hookrightarrow | \subset \mathbb{C}$, is in $1-1$ correspondence with the set P_a [i2] of oriented prediscretifications of π [i3] giving rise to a.

Let us note that every α defines an element $\tau_\alpha \in \Gamma_a$, $\tau_\alpha^2 = 1$ ($\tau_\alpha \neq 1$), hence a canonical map

$$P_a \longrightarrow {}_2\Gamma_a \tag{29}$$

We see that this map is compatible with the action of the group ± 1 on P_a

$$\tau_\alpha = \tau_{-\alpha}$$

If it is true that $\Gamma_{\mathbb{Q}} \xrightarrow{\sim} \Gamma_{g,\nu}$, then [d2] (29) induces by passage to the quotient a bijective map

$$\begin{array}{ccc} P_a/\pm 1 & \xrightarrow{\sim} & \text{set of elements} \\ \| & & \text{of order 2 of } \Gamma_a \\ P_a^\natural = \text{set of prediscretifications} & & \\ \text{(not oriented) over } a) & & \end{array} \tag{30}$$

This comes from the known fact that in $\Gamma_{\mathbb{Q}}$, the only elements of order 2 are the conjugates of τ, and that the centralizer of τ in $\Gamma_{\mathbb{Q}}$ is reduced to $\{1, \tau\}$.

We can say that the datum of a discretification (not oriented) $\alpha^\natural$ over the arithmetization a, amounts to the datum of an [d1] Archimedean valuation on the algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$[i1] defined by (π, a) (i.e. of an isomorphism $\overline{\mathbb{Q}}_1 \simeq \overline{\mathbb{Q}}_0$ modulo complex conjugation)

[p. 192]

30 Properties of the $N_{g,\nu}$, $\Gamma_{g,\nu}$. [m478]

Marginal note. [m478] a) Properties related to finite subgroups|subgroups.

We would like to bring out properties, inspired by the geometrico-arithmetic context, but which can|† [d1] be formulated|formulated in a purely algebraic way – and which are strong enough perhaps to end up characterizing the $N_{g,\nu}$, [d2]

Let us return to a (π, a), an arithmetized group with loops, heuristically, it corresponds to the datum of an algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$, and (if π is given as an outer group) of an algebraic family, parametrized by a universal covering $\widetilde{M}_{g,\nu\overline{\mathbb{Q}}}$[i1] of $M_{g,\nu\overline{\mathbb{Q}}}$, of algebraic curves of type (g, ν). In this perspective, to reduce this family to one algebraic curve – i.e. to give oneself an algebraic curve of type (g, ν) over $\overline{\mathbb{Q}}$ – must amount to giving oneself a kernel of lifting of the surjective homomorphism

$$N_a \longrightarrow \Gamma_a \qquad (\text{kernel } \widehat{\mathcal{T}}_a^+) \tag{1}$$

The datum of such a lifting over an open subgroup Γ', amounts to the datum of an algebraic curve of type g, ν, defined over hum-\|hom- the extension finite $K' \subset \overline{\mathbb{Q}}$ defined by Γ'. ?

It is a matter here not of\|of the arbitrary continuous liftings, but of liftings having particular properties (some of which very deep, of the "Weil" kind…[d1] but perhaps consequences of much simpler properties). The properties †[d2] to be brought out\|†[d3] should in any case be [d4] stable[i1] under passage to a smaller open subgroup. Among these properties, there would be that these\|a germs\|germ of liftings could\|could in their turn be lifted to $\widehat{\widehat{\mathcal{G}}}(\pi)$ itself – in an equally "admissible" way in a sense to be specified – and =\|even that there would be "many" (classes of π-conjugacy)[i2] of such 379

Γ' that are open. We surely want, for such open subgroups

$$\text{ⓑ} \qquad \pi^{\Gamma'} = (1)$$

If we denote by $\tilde{\Gamma}$ the image of Γ in N_a, so that we have an extension (1)

$$1 \longrightarrow \pi \longrightarrow \mathcal{E} \longrightarrow \tilde{\Gamma} \longrightarrow 1, \qquad \Gamma \uparrow \sim$$

we can regard Γ as a section of this extension, Γ' as a partial section. The hypothesis $\pi^{\Gamma'} = (1)$ ensures the rigidity of the category of points of U with values in $\overline{\mathbb{Q}}$, paradigmed by that of germs of splittings|splitting of the extension (1)'.

!|?

We can also look at the sets

$$\widehat{\mathcal{G}}_a^{+\Gamma'} = \mathrm{Centr}_{M_a}(\Gamma') \cap \widehat{\mathcal{G}}_a^{+} \quad \text{and}$$

$$\widehat{\mathcal{T}}_a^{+\Gamma'} = \mathrm{Centr}_{N_a}(\tilde{\Gamma}') \cap \widehat{\mathcal{T}}_a^{+},$$

d2 we thus have an exact sequence

$$(2) \qquad 1 \longrightarrow \pi^{\Gamma'} \longrightarrow (\widehat{\mathcal{G}}_a^{+})^{\Gamma'} \longrightarrow (\widehat{\mathcal{T}}_a^{+})^{\Gamma'}$$

which, taking into account the hypothesis $\pi^{\Gamma'} = (1)$,

[p. 194]

gives

$$(3) \qquad (\widehat{\mathcal{G}}_a^{+})^{\Gamma'} \hookrightarrow (\widehat{\mathcal{T}}_a^{+})^{\Gamma'}.$$

The right-hand side of (3), by our hypothetical dictionary, should be canonically[i1] the|isomorphic group of automorphisms of the curve U over $K'_a|K'$ hence be a finite group, and even d1 the inductive limit (for Γ' decreasing) — which is the group of automorphisms of U over $\overline{\mathbb{Q}}$ — is finite. Denoting by a superscript $\natural$ the corresponding germ of a group, we thus want

$$\text{©} \qquad Z = (\widehat{\mathcal{T}}_a^{+})^{(\Gamma^{\natural})} \left(= \mathrm{Centr}_{N_a|M_a}(\tilde{\Gamma}^{\natural}) \cap \widehat{\mathcal{T}}_a^{+}\right)$$

is a finite group

— which is a counterpart to (b), and expresses that the automorphism groups of the points of $M_{g,\nu\overline{\mathbb{Q}}}$ over $\overline{\mathbb{Q}}$ are finite.

In fact, we would like Z to be conjugate in M_a to a subgroup of to $\mathcal{T}^{+}$ d3 (if we suppose that we have a discretification[i3] d4 π_0 of π, making it possible to define $\mathcal{T}$ — otherwise, we can express this

Let us now pass to finite subgroups of $\widehat{\widehat{\mathcal{G}}}(\pi)$ itself — or at least of M_a — or, what comes to almost the same thing, of $\widehat{\mathcal{G}}_a^+$. We shall, as earlier, restrict ourselves to $G \subset \mathcal{G}(\pi_0)$, for a suitable discretification $\in a$, for otherwise there would be hardly anything to say. We know that then G is cyclic — it|and corresponds to an action of G on a topological U, with fixed point. We can realize it in a complex way, which we will express|express by saying that there exists an admissible lifting $\mathbb{\Gamma}_a^\natural \longrightarrow M_a$, which centralizes G. We know moreover, if $G \neq 1$, that [d2]

$$(5) \qquad \pi^G = (1)$$

(or rather, we know it in the discrete case — we admit it in the profinite context) —

[p. 197]

which we can again interpret as a rigidity property — thus

$$\mathrm{Centr}_{\widehat{\widehat{\mathcal{G}}}}(G) = \widehat{\widehat{\mathcal{G}}}^G \longrightarrow \widehat{\widehat{\mathcal{T}}}^G$$

is injective, so if we have a $\Gamma''|\tilde{\Gamma} \subset N_a|M_a$ which is in the image, then there exists a unique lifting $\Gamma''|\tilde{\Gamma} \longrightarrow \widehat{\widehat{\mathcal{G}}}$ which centralizes G i.e. such that it is $\Gamma \longrightarrow \widehat{\widehat{\mathcal{G}}}^G$.

But in fact what we shall know, for a given $\Gamma \subset M_a$ (defining an algebraic curve via its outer action on a π_1) is that $\Gamma \subset M_a^G$ (i.e. the outer action commutes with a given outer action of G i.e. G operates on the algebraic curve[i1]) — and we would nevertheless like to conclude from this that when we have lifted $G \longrightarrow \widehat{\mathcal{T}}^+$ to|or $G \longrightarrow \widehat{\mathcal{G}}^+$ (i.e. when we have given ourselves a fixed point of the action of G on U): then|therefore the action of $\Gamma^\natural$ lifts (i.e. $\Gamma^\natural \longrightarrow M_a^G$)[i2] automatically|automatic, to $\Gamma^\natural \longrightarrow M_a$[i3] in such a way as to commute|commuting|commuting,.... Is this a property of the choice of the|of the choices of the M_a, or of that of the lifting $\Gamma^\natural \longrightarrow | \hookrightarrow N_a$, or of G??

[scan 390]

In the discrete setting, unless I am mistaken, if we have a faithful action direct|discrete,[i1] of finite G on π_0, then [d1]

$$\mathcal{G}(\pi_0)^G \longrightarrow \mathcal{T}(\pi_0)^G$$

(which is injective, by $\pi_0^G = 1$) is also surjective. No, there is a mistake — that would mean as it stands that if G operates faithfully on a topological surface U of type g, ν, with a fixed point P, then the automorphisms which commute with G fix P (instead of merely permuting the fixed points among themselves...). So we must not expect $\forall$ element of $N_a^G|M_a^G$, nor even of $\widehat{\mathcal{T}}_a^G$, to lift to M_a^G — but rather this: for $G \in | \subset \mathcal{T}_a(\pi_0)$ a given finite subgroup, the π-conjugacy classes of liftings to $\widehat{\mathcal{G}}$, [d2] which are interpreted as fixed points of an action of G on some U, form a finite set, on which $\widehat{\widehat{\mathcal{T}}}(\pi)^G$ operates in a natural way, and the|the stabilizers|stabilizer of a point P i.e. of a conjugacy class of lifting[s]|liftings

[scan 391]

[p. 198] lifts uniquely to $\widehat{\widehat{\mathcal{G}}}^{G}$. This should be reexamined more carefully later on. But it seems to me that we find no new properties here of the $\Gamma \subset \mathcal{M}_a$ or of M_a itself, i.e. of $\mathbb{\Gamma}_a$ as a profinite subgroup of $\Gamma' = \mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}}(\widehat{\mathcal{T}})/\widehat{\mathcal{T}}$.

31 Digression on the liftings of an[i1] outer action of[d1]a[i2] finite group G on a profinite group with loops π.

We assume the outer action faithful, i.e. $G \subset \widehat{\widehat{\mathcal{T}}}(\pi) = \widehat{\widehat{\mathcal{T}}}$, and that $G = G^{+}$.[i3] We assume moreover that there exists an invariant discretification π_0, i.e. such that $G \subset \mathcal{T}(\pi_0)$.

If we assume G cyclic, then unless I am mistaken it is proved that the situation is realizable topologically (thus: algebraically in a complex analytic way ...).

[scan 392]

In the discrete case, the meaning of the π_0-[i1]conjugacy classes of lifting $G \longrightarrow \mathcal{G}(\pi_0)$ is well understood; [d1]likewise for the partial liftings[i2] We find a [d2] canonical[i3] realization of the fundamental groupoid associated to the outer group π_0, by a finite[i4] groupoid $[U^!]$ on which G operates in the strict sense, whose points correspond to the π_0-conjugacy classes of maximal partial sections $\neq 1$, the group [d3]$\mathcal{T}(\pi_0)^G$ operates in an equally canonical way on this groupoid. If $P \in U^!$ corresponds to a lifting $G \longrightarrow \mathcal{G}(\pi_0)$, then an element $\dot{u} \in \mathcal{T}(\pi_0)^G$ is in the image of $\mathcal{G}(\pi_0)^G$, i.e. can be lifted to $u \in \mathcal{G}(\pi_0)$ commuting with G, iff $\dot{u}(P) = P$ [i.e. iff (if $\dot{u}$ is lifted in an arbitrary way to v)[i6] $v(G)$ is π_0-conjugate to G i.e. iff $\exists g \in \pi_0$ such that $v(G) = \mathrm{int}(g)(G)$ i.e. [d5] $u \overset{\text{definition}}{=} \mathrm{int}(g^{-1})v$ fixes G. [d6] (in which case of course it centralizes, (by the hypothesis $\dot{u} \in \mathcal{T}^G$)[i7]) Thus our brilliant assertion, is a tautology] if $U^! \neq \emptyset | \phi$

[scan 393]

[p. 199] and hence the lifting is unique. As $U^!_{*|\varphi}$ is finite, hence the stabilizer $\mathcal{T}(\pi_0)^G_P$ of P in $\mathcal{T}(\pi_0)^G$ has finite index, and so it is this subgroup of finite index that lifts merrily and canonically.

What can one say in the profinite context? Of course, we have a canonical map

$$\begin{array}{c}\text{classes of } \pi_0\text{-conjugacy}\\ \text{of liftings of}\\ G \text{ into } G \longrightarrow \mathcal{G}(\pi_0)\\ \text{i.e. of splittings of}\\ \text{the extension } 1 \longrightarrow \pi_0 \longrightarrow E \longrightarrow G \longrightarrow 1\end{array} \longrightarrow \begin{array}{c}\text{classes of } \pi_0\text{-}\\ \text{conjugacy of liftings of}\\ G \text{ into } G \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi_0)\\ \text{i.e. of splittings}\\ \text{of the extension}\\ 1 \longrightarrow \begin{array}{c}\widehat{\pi}_0\\ \|\\ \pi\end{array} \longrightarrow \widehat{E} \longrightarrow G \longrightarrow 1\end{array}$$

We should first examine

a) The question of the bijectivity of this map.

b) The question whether $\pi^G = 1$ (rigidity|rigidity), for $G \neq (1)$. – (for a given lifting, in E for simplicity)

I feel like conjecturing shamelessly that this is so — which would imply for example that for every such lifting G, there is

[p. 200]

32 Return to the arithmetic aspects of plugging holes: relations between $\Gamma_{g,\nu}$ and $\Gamma_{g,\nu-1}$.

Of course, we [d1] have that

$$\mathcal{N}_{g,\nu} \longrightarrow \mathfrak{S}_{\nu}$$

is surjective (since $\mathcal{T}_{g,\nu} \longrightarrow \mathfrak{S}_{\nu}$ is)[i1], hence we will have

$$(1) \qquad 1 \longrightarrow |-\mathcal{N}'_{g,\nu} \longrightarrow |-\mathcal{N}_{g,\nu} \longrightarrow |-\mathfrak{S}_{\nu} \longrightarrow |-1$$

and the Cartesian diagram of subgroups of $\widehat{\widetilde{\mathcal{T}}}_{g,\nu}$

$$(2) \qquad \begin{array}{ccc} \widehat{\mathcal{T}}^{+}_{g,\nu} & \hookrightarrow & \mathcal{N}_{g,\nu} \\ \uparrow & & \uparrow \\ \widehat{\mathcal{T}}^{!+}_{g,\nu} & \hookrightarrow & \mathcal{N}'_{g,\nu} \end{array}$$

m488

Marginal note. [m488] [d2] $\mathcal{N}_{g,\nu} = \mathcal{N}'_{g,\nu} \cdot \widehat{\mathcal{T}}^{+}_{g,\nu}$ i.e. $\mathcal{N}_{g,\nu}$ known from $\mathcal{N}'_{g,\nu}$

will give an isomorphism

$$(3) \qquad \mathcal{N}'_{g,\nu}/\widehat{\mathcal{T}}^{!+}_{g,\nu} \xrightarrow{\sim} \mathcal{N}_{g,\nu}/\widehat{\mathcal{T}}^{+}_{g,\nu} = \mathbb{\Gamma}_{g,\nu}$$

In the case of a (π, a), (π an outer group with loops,[i2] a an arithmetization), we will likewise have

$$(4) \qquad \begin{cases} \mathcal{N}_a^!/\widehat{\mathcal{T}}_a^+ \simeq \mathcal{N}_a/\widehat{\mathcal{T}}_a^+ = \mathbb{\Gamma}_a. \\ \mathcal{N}_a = \mathcal{N}_a^! \widehat{\mathcal{T}}_a^+ \end{cases}$$

Let us now consider [d3] for $\forall i \in I$ the stabilizer [d4] $\mathcal{N}_i$ of i in $\mathcal{N}$, and the group [d5] with loops (not outer!)[i4] π_i' of type $g, \nu - 1$, deduced from π by "plugging hole i", [m489]

Marginal note. [m489] We write $\mathcal{N}$ etc. instead of $\mathcal{N}_a$. We assume [illeg. 2] $(g, \nu - 1)$, i.e. $2g - 2 + \nu$ [illeg. 1] ≥ 1, i.e. $2g + \nu \geq 4$

[scan 399]

[p. 202]

(perhaps!) a faithful representation of $\mathbb{\Gamma}_{\mathbb{Q}}$. But until an indication to the contrary, I prefer to work hypothetically with (f), which is expressed by the fundamental exact|exact sequences

$$(9) \qquad 1 \longrightarrow \hat{\pi}_{g,\nu-1} \overset{\varphi_i}{\longrightarrow} \mathcal{N}^!_{g,\nu} | \mathcal{M}^!_{g,\nu} \overset{\psi'_i}{\longleftrightarrow} | \overset{\psi'_i}{\longrightarrow} \mathcal{N}^!_{g,\nu-1} | \mathcal{M}^!_{g,\nu-1} \longrightarrow 1$$

m494

Marginal note. [m494] & we could include it in a slightly larger exact sequence, with $(\mathcal{N}_{g,\nu})_i$ and $\mathcal{N}_{g,\nu-1}$ ...

which extends the exact|exact sequence

$$(10) \qquad 1 \longrightarrow \hat{\pi}_{g,\nu-1} \overset{\varphi_i}{\longrightarrow} \widehat{\mathcal{T}}^!_{g,\nu} \overset{\psi'_i}{\longrightarrow} \widehat{\mathcal{T}}^!_{g,\nu-1} \longrightarrow 1$$

(and takes the place of the perhaps failing exact|exact sequence

$$?? \qquad 1 \longrightarrow \hat{\pi}_{g,\nu-1} \longrightarrow \widehat{\widehat{\mathcal{T}}}^{!}_{g,\nu} \longrightarrow \widehat{\widehat{\mathcal{T}}}^{!}_{g,\nu-1} \longrightarrow 1 \qquad ??$$

)

When (π, a) is an outer group with loops equipped with an arithmetization – what one could call a "virtual algebraic curve" – then what precedes allows us to define, on each[i1] of the π'_i of type $(g, \nu-1)$ associated to the $i \in I(\pi)$, an arithmetization canonically associated to a, say a',

[p. 203]

arithmetizations|arithmetization of π'_i — which would amount to the bijectivity of

$$\widehat{\widehat{\mathcal{T}}}/\mathcal{N}_a \longrightarrow \widehat{\widehat{\mathcal{G}}}/M^{\natural}_{a'}|M^{\sharp}_{a'} \simeq \widehat{\widehat{\mathcal{T}}}/\mathcal{N}_{a'},$$

which would[i1] hardly have any reason to be except if one admitted $\widehat{\widehat{\mathcal{T}}}(\pi) \xrightarrow{\sim} \widehat{\widehat{\mathcal{G}}}|\widehat{\mathcal{G}}(\pi'_i)$, which seems quite problematic to me.

m495

Marginal note. [m495]

However, one finds, by the "plugging the holes" functor, an equivalence between the category of [d1] outer arithmetized profinite groups with loops, of type (g,ν),[i2] and of arithmetized profinite groups with loops (not outer!), of type $(g,\nu-1)$.

One can propose to try to specify [d2] the type of properties which will characterize $\mathcal{N}_{g,\nu}$ in $\mathcal{N}'_{g,\nu} = \mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}_{g,\nu}}(\widehat{\mathcal{T}}^{+}_{g,\nu})$, [d3] [d4]or again[i3] $\Gamma_{g,\nu}$ [d5] in $\Gamma'_{g,\nu} = \mathcal{N}'_{g,\nu}/\widehat{\mathcal{T}}^{+}_{g,\nu}$. We have natural homomorphisms 400

[scan 405]

[p. 205] admissibility.

Preliminary question Knowledge of π, of $\underbrace{\widehat{\mathcal{T}}_a^+}_{\Sigma_a} \subset \widehat{\widehat{\mathcal{T}}}(\pi)$, and of a subgroup $\Gamma' \subset \widehat{\widehat{\mathcal{T}}}(\pi)$ (normalizing Σ_a, such that $\Gamma' \cap \Sigma_a | \Sigma_\bullet = (1)$[i1]) would it make it possible to recover the arithmetization|arithmetization of π — and, to begin with, to recover $\mathcal{N}_a$ (in which $\Gamma' \cdot \Sigma$ is of finite index)? [d1] It would suffice|will suffice, to be able to answer in the affirmative, to know that every outer isomorphism $\pi \longrightarrow \pi_{g,\nu}$, which sends Σ onto $\widehat{\mathcal{T}}_{g,\nu} = \Sigma_{g,\nu}$, and[i2] every|the subgroup of finite index $\Gamma' \cdot \Sigma$ in $\mathcal{N}_a$ into $\mathcal{N}_{g,\nu}$, is compatible with the arithmetizations|arithmetizations. Now this amounts exactly|exactly to:

Ⓖ (optional, all the same!) [d2] For every open subgroup $\mathcal{N}'$ of $\mathcal{N}_{g,\nu}$, the elements of $\widehat{\widehat{\mathcal{T}}}_{g,\nu}$ normalizing $\widehat{\mathcal{T}}_{g,\nu}$ and[i3] which carry $\mathcal{N}'$ into $\mathcal{N}_{g,\nu}$, are in $\mathcal{N}_{g,\nu}$ (a fortiori, $\mathcal{N}_{g,\nu}$ would be its own normalizer in $\mathrm{Norm}_{\widehat{\widehat{\mathcal{T}}}_{g,\nu}}(\widehat{\mathcal{T}}_{g,\nu})$). 404

[scan 406]

With the "points of U" (defined as conjugacy classes of "admissible" liftings (19) i.e. satisfying (20), one makes a groupoid, having π as its outer fundamental group, and on which $\Gamma^{\natural|\sharp} \subset \mathcal{N}_a$ operates strictly (N.B. to take a rest, one now gives oneself $\Gamma^{\natural}|\Gamma$ itself, not only|only a germ — morally|morally, this means that one has a curve defined over a finite subextension K of $\overline{\mathbb{Q}}/\mathbb{Q}$ …}|). The fixed points of Γ correspond to the rational points/K, the fixed points under a closed subgroup Γ' to the points rational over the subextension K' of $\overline{\mathbb{Q}}/\mathbb{Q}$ associated with Γ' …) 405

[scan 407]

[p. 206]

Now let

$$\boxed{I' \subset I = I(\pi)}$$

be a subset of I, stable under Γ. One finds by "plugging the holes at I'" an outer group with loops π', [d1] and an outer homomorphism

$$(20) \qquad \pi^{\natural|\sharp} \longrightarrow \pi'$$

Besides, π' inherits an arithmetization a'^{i1} from π – and we shall have

$$(21) \qquad \begin{cases} \mathbb{\Gamma}_a & \overset{\sim}{\longrightarrow} & \mathbb{\Gamma}_{a'} \\ \mathbb{P}_a & \overset{\sim}{\longrightarrow} & \mathbb{P}_{a'} \\ \wr & & \\ P & & \end{cases} \rightsquigarrow$$

so π' is defined over the|the same P as $\mathbb{\Gamma}_a$ (i.e. by making holes in U to find U', we have not disturbed the algebraically closed|absolute base field $\overline{\mathbb{Q}}$…). Besides we shall have a canonical homomorphism

$$\widehat{\mathcal{T}}(\pi) \longrightarrow \widehat{\mathcal{T}}(\pi')$$

inducing

$$(22)$$

$$\begin{array}{ccc} \mathcal{N}_a & \longrightarrow & \mathcal{N}_{a'} \\ \cup & & \cup \\ \widehat{\mathcal{T}}_a & \longrightarrow & \widehat{\mathcal{T}}_{a'} \end{array}$$

[p. 209]

admissible, if the outer action deduced is.

We thus find an equivalence between the category of [d1] systems $(\pi, a, \Gamma, \psi, i)$ of a (π, a) of type $(g, \nu+1)$, with an admissible outer[i1] operation ψ of a Γ on it, and an $i \in I(\pi)$ stable under Γ, with the category of $(\pi', a', \Gamma, \psi')$ of (π', a') of type (g, ν), with a genuine admissible action ψ' of Γ on it.

[d2] Condition (1) ensures that[i2] [d3] if Γ operates [d4] [d5] actually, in a way[i3] admissible, then the outer action deduced is admissible (but the converse will not be true – there will be "pathological" liftings of a given admissible categorical|outer action…). We suppose moreover

m514

Marginal note. [m514]

③ If Γ operates actually[i4] in an admissible way on π, then $\pi^{\Gamma} = (1)$.

[d6] This implies that the category of Γ-Points of π, or if you like of sections of $B_{\pi,\Gamma}$ $(\simeq B_u)$ over B_Γ, is rigid.

[scan 417]

[p. 211]

(26)

[The horizontal segments issuing from the two 1 on the left have no visible arrowhead. The right ends of the segments π–$M_a(\pi)_i$ at the top, $M_{a'}(\pi'_i)$–$N_{a'}(\pi'_i)$ and $N_{a'}(\pi'_i)$–1 at the bottom are thickened, with no arrowhead legible with certainty. An ink blot (overwriting) follows the parenthesis of $M_a(\pi)_i$. The word commutative is written in the right-hand triangle, between the dotted arrow and the right-hand vertical arrow; it is not a legible label of the dotted arrow.]

.

This being so, if we have an admissible outer[i1] operation $\Gamma \longrightarrow N_a(\pi)$ of Γ on π, fixing i,[i2] hence also through $N_a(\pi) \longrightarrow N_{a'}(\pi'_i)$ on π'_i, we can consider that †[d1] lifting $\Gamma \longrightarrow M_a(\pi)$ for π[i3] defines by composition a lifting $\Gamma \longrightarrow M_{a'}(\pi'_i)$ for π'_i. [d2] We easily conclude from[i4] ② that if the first is admissible, the second is. We thus find

$$(27) \qquad \mathrm{Pt}_{\mathrm{ad}}(B_{\pi,\Gamma}) \longrightarrow \mathrm{Pt}_{\mathrm{ad}}(B_{\pi'_i,\Gamma})$$

(and passing to the limit, a map of Γ-sets

$$(28) \qquad \mathrm{Pt}_{\mathrm{ad}}(B_{\pi,\Gamma^\natural}) \longrightarrow \mathrm{Pt}_{\mathrm{ad}}(B_{\pi'_i,\Gamma^\natural})$$

– which moreover corresponds to a homomorphism of Γ groupoids

$$(29) \qquad \underline{\mathrm{Pt}}_{\mathrm{ad}}(B_{\pi,\Gamma^\natural}) \longrightarrow \underline{\mathrm{Pt}}_{\mathrm{ad}}(B_{\pi'_i,\Gamma^\natural}).$$

This being so, let $P \in \mathrm{Pt}_{\mathrm{ad}}(B_{\pi'_i,\Gamma})$ be the "canonical point" of $\mathrm{Pt}_{\mathrm{ad}}B_{\pi'_i,\Gamma} = (\mathrm{Pt}_{\mathrm{ad}}(B_{\pi'_i,\Gamma^\natural}))^\Gamma$.

[scan 418]

We ask:

⑤ The map (27) induces a bijection.

$$\mathrm{Pt}_{\mathrm{ad}}(B_{\pi,\Gamma}) \longrightarrow \mathrm{Pt}_{\mathrm{ad}}(B_{\pi'_i,\Gamma}) \setminus \{P\}$$

or again (passing to the limit) a bijection of Γ-sets

$$\mathrm{Pt}_{\mathrm{ad}}(B_{\pi,\Gamma^\natural}) \simeq \mathrm{Pt}_{\mathrm{ad}}(B_{\pi'_i,\Gamma^\natural}) \setminus \{P\}$$

This means three things:

a) The canonical homomorphism $\Gamma \longrightarrow M_{a'}(\pi'_i)$, the composite of $\Gamma \longrightarrow N_a(\pi)$ and $N_a(\pi) \simeq M_{a'}(\pi'_i)$, is not π'_i-[i1]conjugate to a composite homomorphism $\Gamma \overset{\lambda}{\to} M_a(\pi) \overset{\varphi_i}{\longrightarrow} M_{a'}(\pi'_i)$, where $\Gamma \overset{\lambda}{\to} M_a(\pi)$ is an admissible lifting.

b) If $\lambda, \mu : \Gamma \rightrightarrows M_a(\pi)$ are two admissible liftings of $\Gamma \longrightarrow N_a(\pi)$ [d1] such that $\varphi_i \circ \lambda$ and $\varphi_i \circ \mu : \Gamma \rightrightarrows M_a(\pi)$ are π'_i-[i2]conjugate, then λ and μ are already π-[i3]conjugate.

c) Every admissible lifting of $\Gamma \longrightarrow N_{a'}(\pi'_i)$ to $\Gamma \longrightarrow M_{a'}(\pi'_i)$, comes by composition from an admissible lifting $\Gamma \longrightarrow M_a(\pi)$.

[p. 212]

Thanks to this, the equivalence of categories between systems $(\pi, a, i, \Gamma, \theta : \Gamma \underset{\mathrm{adm}}{\longrightarrow} N_a)$, and the systems $(\pi', a', \Gamma, \theta' : \Gamma \longrightarrow N_{a'}, P)$, where $P \in \mathrm{Pt}(B_{\pi',\Gamma^\natural})^\Gamma$, becomes perfectly precise at the level of points: the Γ-rational Points of $B_{\pi,\Gamma^\natural|\dagger}$ are identified with one|the set [d2] of the Γ-rational points of $B_{\pi'}$, distinct from P.

This then allows us (which was not feasible in the discrete context!) to extend the equivalence of categories to an equivalence

category of systems $(\pi, a|\alpha, I', \Gamma, \theta : \Gamma \longrightarrow \cong | \simeq$ category of systems $(\pi', a'|\alpha', I', \Gamma^*|\Gamma, \theta' : \Gamma \longrightarrow N_{a'})$ of an arithmetized π (by $\alpha|a$)[i1] of type (g, ν), of $I' \subset I(\pi)$, of an admissible outer action of Γ on π such that Γ [d3] fixes each point of I' of an arithmetized π' (by $a'|\alpha'$) of type (g, ν') $[\nu' = \nu - \mathrm{card}(I')]$ with an admissible outer[i2] operation of Γ on it, and a subset $I' \subset \mathrm{Pt}_{ad}(B_{\pi',\Gamma})$ (hence $I' \subset \mathrm{Pt}_{ad}(B_{\pi',\Gamma})^{\Gamma}$) i.e. I' formed of points invariant|fixed under Γ, i.e. "Γ-rational"

m516

Marginal note. [m516] with $2g + (\underbrace{\nu - \mathrm{card}\, I'}_{\nu'}) \geq 3$

We thus have a quasi-inverse functor: drilling holes at I' !

[scan 420]

It is to be noted that in this approach, we have had to restrict ourselves to the case [d1] of a set of[i1] points [d2] $I' \subset I(\pi)$ not only stable under Γ, but [d3] $\subset I^{\Gamma}$ [d4] or again to a subset $I' \subset \mathrm{Pt}(B_{\pi',\Gamma^{\natural}})$ not only stable under Γ, but even|$= \subset \mathrm{Pt}(B_{\pi',\Gamma^{\natural}})^{\Gamma}$. To show that without this restriction, the natural functor [d5] that corresponds is nevertheless an equivalence, we are reduced to this

⑥ Let $(\pi, a, I' \subset I(\pi))$ be with (π, a) an arithmetized categorical[i2] profinite|profinite group with loops of type g, ν, whence (π', a') — let Γ be, with Γ' an open subgroup operating on (π, a) in an admissible way $(\Gamma \longrightarrow N_a(\pi))$, and leaving I' stable, hence it operates in an admissible way on (π', a'), Suppose given a lifting of this action of Γ' to an admissible action of Γ on $N_{a'}$, which leaves invariant

$$I' \subset \mathrm{Pt}(B_{\pi',\Gamma^{\natural}}).$$
$$\wr|$$
$$\mathrm{Pt}(B_{\pi',\Gamma'^{\natural}})$$

Then there exists a unique admissible action of $\Gamma|\Gamma'$ on (π, a), which extends that of Γ' and which gives rise to the given[i3] one on π'.

Scans 421–430

[scan 421]

[p. 213] [d1] Is uniqueness at all|all events clear? [d2] Let us consider the extension $\mathcal{E}$[i1] of Γ by $L = \mathrm{Ker}((N_a)_{I'} \to N_a|N_0)$, inverse image of the extension $(N_a)_{I'}$ (of $N_{a'}|N_{0'}$ by L) via $\Gamma \to N_{a'}|N_{0'}$, we have a partial[i2] splitting of this extension over the subgroup Γ' of Γ, and the assertion is that this splitting extends, in a way that is unique, to Γ. We may suppose Γ' normal in Γ, and we identify Γ' with a subgroup of $\mathcal{E}$. All [d3] the sections of $\mathcal{E}$ over Γ are identified with section[i3] subgroups $\tilde{\Gamma}$ of $\mathcal{E}$. For such a $\tilde{\Gamma}$, we have of course $\tilde{\Gamma} \subset \mathrm{Norm}_{\mathcal{E}}(\Gamma')$ moreover [d4] we obviously have[i4]

$$\mathrm{Norm}_{\mathcal{E}}(\Gamma') \cap L = L^{\Gamma'} \tag{31}$$

and I presume we must have $L^{\Gamma'} = 1$ (which generalizes condition ③ above…) Now this condition implies uniqueness – namely $\tilde{\Gamma} = \mathrm{Norm}_{\mathcal{E}}(\Gamma')$ – and existence means that $\mathrm{Norm}_{\mathcal{E}}(\Gamma') \to \Gamma$ is an epimorphism (hence an isomorphism…).

But we will have to try to make precise, in certain contexts (at least that of

[scan 422]

arithmetically faithful actions, i.e. $\Gamma \to \mathbf{\Gamma}_a$ injective – which corresponds normally|presumably to the case of algebraic curves defined over algebraic extensions of $\mathbb{Q}$ – the notion of an "admissible" action. For this, we must return to the relation between (potential) curves and finite coverings, which also gives a way of varying g.

But I feel like first taking up again under|on another aspect (perhaps more general)[i1] the preceding formalism, which can perhaps also be applied to the case of discrete groups with loops (I am thinking of the formalism of the $U^!|\mathcal{U}^!$, linked to outer actions of finite groups on such profinite groups with loops).

Let $\mathcal{X}$ be a set $\neq \emptyset$[i2] (morally, a[i3] set of the "points" of an [d1] algebraic curve, or of a topological surface…), [d2]

d1

$\forall$ homomorphism of plugging holes at $i \in I(\pi)$, $\pi \longrightarrow \pi'_i$, $N(\pi)_i \longrightarrow M(\pi'_i)$, the corresponding homomorphism Γ_i, nor of any open subgroup Γ' of Γ_i, does not normalize an L'_j $(j \in I(\pi'_i) = I \setminus \{i\})$.

perhaps we would even have to impose $\pi^{(\Gamma'^+)|\langle\Gamma'^+\rangle} = (1)$, where Γ'^+ is the kernel of $\Gamma' \xrightarrow{\chi} \widehat{\mathbb{Z}}^*$ — in any case we expect — that we then have $\pi^{\Gamma'} = (1)$, and if this were not the case, we would have to introduce it into the definition — for each operation of plugging holes relative to $I' \subset I(\pi)$, and to the choice of an $i \in I'$, allowing us to define $\Gamma_{(I',i)} \longrightarrow M(\pi(I'))$.

m522

Marginal note. [m522] More generally, for $i \in I' \subset I = I(\pi)$, [d5] we impose[i3] that the true action of $\Gamma_{I',i}$ on $\pi_i(I')|\Pi_i(I')$ corresponding[i4] to i normalize no subgroup L_j $(j \in I \setminus I')$ — we are reduced for this to the case where $I' = I \setminus \{j\}$, hence where $\pi(I')|\Pi(I')$ has (only a single class loops… (if|and $g \geq 1$)

Let us note that a true action of Γ on π (not only|only outer) which lifts a given+ admissible action, is it too[i5] admissible (in the sense that it defines an [d6] admissible action on a π' of type $(g, \nu + 1)$), iff this action (rather its germ)[i6] normalizes no L_i $(i \in I(\pi))$, and that

[scan 434]

indeed, it suffices to look at a parameter scheme S, of finite type over $Q|\mathbb{Q}$ (a $K(\pi,1)$ preferably, for example an algebraic curve) and to take for Γ (not the fundamental group of its generic point, i.e. of a field,[i1] but) the fundamental group of S itself. The datum of an admissible outer action of Γ on a π corresponds morally to that of a family of curves U of type g, ν parameterized by S. Condition c) is satisfied for example if U comes from an algebraic curve over the base field itself, so no problem – and it is plain that surjectivity goes haywire. The difficulty comes from the fact that two distinct sections of U over S may not be disjoint !

m527

Marginal note. [m527] The splittings of extensions correspond to the sections of U over S

[scan 435]

[p. 220]

One must be able to speak of sections "strictly|strictly distinct" i.e. distinct at every point of S – which, in profinite translation, amounts to comparing two splittings of the extension of Γ by π, with [d1]the[i1] germs of[i2] splittings over $\mathbf{\Gamma}'_{\cdot} \subset \mathbf{\Gamma}|\mathbf{\Gamma}' \subset \mathbf{\Gamma}$ of Γ (as an extension of $\mathbf{\Gamma}_Q$ by a geometric part) which correspond to the points of S – i.e. precisely the admissible (germs of splittings). One has the impression of going around in a vicious circle or almost – it would seem that one should not try to swallow too much at once – deal from the outset with all profinite groups Γ at once – but rather restrict oneself first[i3] to those which, morally, correspond to $\pi_1|\Pi_1$ of[i4] schemes of finite type over $Q|\mathbb{Q}$ – some $K(\pi,1)$ let us say, or even[i5] varieties

elementary in Artin's sense – and in the definitions resp. conjectures, pull oneself up by one's shoelaces, by inducting on the dimension.

At the first notch then (dimension 0) one would restrict oneself to actions of groups Γ which are (modulo at least passage to an open subgroup) "arithmetically faithful" for example|for example $\Gamma \to \mathbf{\Gamma}_a$ injective.

In|In that case, the conjecture as stated just now seems reasonable, or at least not necessarily crazy. The decisive test,|,: it is true, would be the possibility of obtaining the "curves" thus defined as coverings of $\mathbb{P}^1 \setminus \{0, 1, \infty\}$ …

[scan 437]

[p. 221]

33 Topological digression : Anti-involutions of oriented algebroid surfaces

m528

Marginal note. m528 In the end I look only at compact surfaces – Yet the noncompact case would also be very interesting to look at – to try to recover by an "algebraic" route, from the outer automorphism of order 2 in π_1, the arrangement of the curve's "points at infinity" on the connected components of d1 X^σ $(X = \widehat{U})$

We call an algebroid surface a surface U of the form $\widehat{X} \setminus S$, X a compact orientable surface[i1], S finite. Then X is determined up to unique homeomorphism as the "pure compactification" of U, denote it|we denote it $\widehat{U}$. d2 The homeomorphisms of U onto itself are identified with the morphisms of X which map S into itself. The orientations of X are in 1-1 correspondence with those of U. The anti-involutions of U (assumed oriented) are in 1-1 correspondence with those of X which preserve S.

We then find an equivalence between the category of oriented algebroid surfaces U,[i2] equipped with an anti-involution σ, and of compact surfaces with boundary Y, equipped with a finite subset T, to (U, σ) corresponds $(\widehat{U}/\sigma, (\widehat{U} \setminus U)/\sigma)$ – and to (Y, T) corresponds $\tilde{Y} - \tilde{T}$, where $\tilde{Y}$ is the "oriented double" of Y (which is a compact oriented surface)[i3], and $\tilde{T}$ the inverse image of T in $\tilde{Y}$.

We are now interested in the

[scan 438]

case where U is connected of type (g, ν), first examining the case $\nu = 0$, i.e. $U = \widehat{U}$, $S = \emptyset$[i1] (to which the general case will reduce). [d1] The condition $\nu = 0$[i2] corresponds to the case where $T = \emptyset$ – thus the $U = X$[i3] [d2] considered [d3] are identified with the oriented doublings of certain compact manifolds with boundary Y. Which ones ? Obviously Y must be connected, and nonorientable.

m529

Marginal note. [m529] it is not true that Y is necessarily nonorientable – only in the case where $X^\sigma = \emptyset$

So Y is characterized, up to homeomorphism, by its genus γ and the number μ of connected components of the boundary[i5i4] – it can be obtained from the projective plane Y_0 over the reals[i6] by cutting out γ disjoint disks in it, and gluing Möbius strips back in, then removing again μ open disks,[i7] – which gives

$$\chi(Y) = \underset{1}{\chi(Y_0)} - \gamma \cdot \underbrace{\chi_!(\text{open disk})}_{+1} + \gamma\chi_!(\text{open Möbius strip}) \\ +|-\mu \underbrace{\chi_!(\text{open disk})}_{+1}$$

now the open[i8] Möbius strip (obtained from Y_0 by removing a closed[i9] disk) has a|a $\chi_!$ equal to :

$$\underset{1}{\chi(Y_0)} - \underset{1}{\chi(\text{closed disk})}, \quad \text{i.e. } 0, \quad \text{hence}$$

$$(1) \qquad \chi(Y) = 1 - (\gamma + \mu)$$

m530

Marginal note. [m530] Y compact connected nonorientable surface without boundary of genus γ

On the other hand, we will have|have

$$\chi(X) = \chi(X \setminus X^\sigma)$$

for X^σ is a union of circles so its χ is zero,

[p. 222]

Now, since $X \setminus X^\sigma$ is an étale covering of order 2 of Int Y, we have

$$\chi(X \setminus X^\sigma) = 2\chi(\mathrm{Int}(Y))$$

finally

$$\chi(Y) = \chi(\underline{Y \setminus \partial Y}) = \chi(\mathrm{Int}\, Y)$$

for the same reason as before ($\chi(\partial Y) = 0$), hence finally

$$(2) \qquad \chi(X) = 2\chi(Y) = 2(1 - (\gamma + \mu))$$

[d1] or again, since $\chi(X) = 2 - 2g$

$$(3) \qquad g = \gamma + \mu$$

Thus we find [illeg. 1]

Proposition The category of oriented connected compact[i1] surfaces of genus g equipped with an anti-involution σ is equivalent to that of nonorientable compact manifolds with boundary, of type (γ, μ) (γ the genus, μ the number of holes), with $\gamma + \mu = g$.

m532

Marginal note. m532 no, we find only a full subcategory of that of all the (X, σ). On the other hand there are also the oriented doublings $Y \amalg_{\partial Y} Y$ of compact orientable surfaces with nonempty boundary – if Y is of type (γ, μ), X is of genus g with $g = 2\gamma + \mu - 1$ (where $\gamma \geq 0$, $\mu \geq 1$)

Corollary There are exactly $g + 1$ isomorphism classes of systems (X, σ), classified by $0 \leq \mu \leq g$, where $\mu = \operatorname{card} \pi_0 | \Pi_0(X^\sigma)$.
m533

Marginal note. m533 This only works by restricting oneself to the (X, σ) such that (X/σ) nonorientable – cf.|cf. opposite d2 the d3 case X/σ orientable i2

$X = X_g$ i3 is a compact oriented surface of

[p. 223]

of topological automorphisms of $\widetilde{U}$ compatible with the equivalence relation defined by $\widetilde{U} \longrightarrow |-U$, and inducing on U the automorphism id_U or σ.

d1 Then

a) (For the record) U^σ is a closed submanifold of U of dimension 1.

b) For $\forall\ x \in U^\sigma$, one finds a π-i1conjugacy class of d2splittingsi2 of the extension $\mathcal{E}$, in the usual way, whence a map d3

$$\begin{aligned} U^\sigma \longrightarrow \mathrm{Sc}(\mathcal{E}, \mathbb{Z}/2) = {} & \text{set of classes under} \\ & \pi\text{-conjugation of splittings of } \mathcal{E} \\ & \text{over } \mathbb{Z}/2, \text{ or again of} \\ & \text{elements of order 2 of} \\ & \mathcal{E} \text{ which are not in } \pi. \end{aligned} \tag{5}$$

This map factors through a bijection

$$\pi_0(U^\sigma) \simeq \mathrm{Sc}(\mathcal{E}, \mathbb{Z}/2) \tag{6}$$

c) Let Z_i be a connected component of U^σ, corresponding to a d4 $\sigma_i \in \mathcal{E}^-$ d5ofi3 order 2. Then d6

$$\pi^{\sigma_i} = \{1\} \quad \text{sss|iff} \quad Z_i \simeq \mathbb{R}, \tag{7}$$

d) If $Z_i \not\simeq \mathbb{R}$ i.e. d8 $Z_i \simeq S^1|\mathbb{S}^1$, then, for a chosen orientation of Z_i, denot-

ing by g_i the element of $\pi = \pi_1(U)$ that it defines (defined up to conjugation), and by $\varphi_i : \mathbb{Z} \longrightarrow \pi$ the homomorphism $\varphi_i(n) = g_i^n$ from $\mathbb{Z}$ to π, one has:

1°) φ_i is injective

2°) after possibly replacing φ_i by a conjugate, one has

$$(9)|(8) \qquad \pi^{\sigma_i} = \operatorname{Im} \varphi_i$$

Proof One finds the map (5) by [d1], for $\forall\ x \in U^\sigma$, the canonical[i1] operation of $\mathbb{Z}/2$ on the universal covering $\widetilde{U}(x)$ pointed at x, and by [d2] taking the corresponding operations on $\widetilde{U}$, deduced via the isomorphisms $\widetilde{U} \simeq \widetilde{U}(x)$. One sees that the [d3] operations σ'[d4] obtained on $\widetilde{U}$ (for fixed x)[i2], are those for which [d5] $\widetilde{U}^{\sigma'}$ has a point over x — hence the set of x which give rise to [d6]the[i3] class of a σ', are the elements of the image of $\widetilde{U}^{\sigma'}$ under the projection $\widetilde{U} \longrightarrow U$. Since by the lemma $\widetilde{U}^{\sigma'}$ is nonempty and connected, it follows that

[p. 224] its image in U^σ is so too — we are going to see that its image is exactly a connected component of U^σ — which will prove both the factorizability of (5) through [d1] $\pi_0(U^\sigma)$ (rather trivial in any case) and the fact that the resulting map (6) is bijective.

Let $\widetilde{Z}_i$ be a universal cover[ing]|covering of Z_i, and let us take the corresponding universal covering $\widetilde{U}_i$ of U, so that one has (8)|(9)

$$\begin{array}{ccc} \widetilde{Z}_i & \longrightarrow & \widetilde{U}_i \\ \downarrow & & \downarrow \\ Z_i & \longrightarrow & U \end{array}$$

and by functoriality σ also operates on this diagram (operating trivial[ly] on $Z_i, \widetilde{Z}_i$), let σ_i be its operation on $\widetilde{U}_i$. One thus sees that $\widetilde{Z}_i$ maps into $\widetilde{U}_i^{\sigma_i}$, which therefore maps onto Z_i — which already finishes proving b).

[d3] Let us consider [d4] the image[i2] [d5] of $\widetilde{Z}_i$ in $\widetilde{U}_i|\widetilde{U} \mid Z_i$, this is an open and closed subset[i1] (as the image of a morphism of étale cover[ings]|coverings over the same component Z_i), so it is

fortiori an open and closed subset of $\widetilde{U}_i^{\sigma_i}$, and since this space is connected, it is equal to it. d1 d2 Moreover $\widetilde{Z}_i \longrightarrow \widetilde{U}^{\sigma_i}$ makes d3of i2 $\widetilde{Z}_i$ an étale covering of its image $\widetilde{U}_i^{\sigma_i}$ in $\widetilde{U}_i \mid Z_i, *$ and since $\widetilde{U}_i^{\sigma_i}$ is simply|simply connected, one finds finally|finally

$$(10) \qquad \widetilde{Z}_i \xrightarrow{\sim} \widetilde{U}_i^{\sigma_i}$$

i1

When Z_i is simply|simply connected i.e. $\widetilde{Z}_i \simeq Z_i$, this also means that $\widetilde{U}_i^{\sigma_i} \longrightarrow Z_i$ is a homeomorphism, (thus $\widetilde{Z}_i = Z_i \longrightarrow \widetilde{U}_i^{\sigma_i}$ is the inverse homeomorphism). Since, for $x \in Z_i$, d4 and $\tilde{x} \in (\widetilde{U}_i^{\sigma_i})_x$, the $\tilde{x}'$ of $\widetilde{U}_i^{\sigma_i}$ over x are d5 the elements i3 of the form $\tilde{x} \cdot \gamma$, with $\gamma \in \pi_i^{\sigma_i}$ ($\pi_i = \mathrm{Aut}(\widetilde{U}_i/U)$) it follows that one indeed has

$$(11) \qquad \pi_i^{\sigma_i} = 1$$

which is essentially formula (7).

In the case d6 Z_i not simply|simply connected, i4 setting

$$(12) \qquad T_i = \mathrm{Aut}(\widetilde{Z}_i/Z_i) \underset{f}{\simeq} \pi_1(Z_i; \widetilde{Z}_i)$$

one finds a canonical homomorphism

$$(13) \qquad \varphi_i : T_i \longrightarrow \pi_i$$

and injectivity in (10) is equivalent to (13) being injective. Of course,

[p. 225] the choice of a generator g_i° of T_i amounts to the choice of an orientation of Z_i, and $g_i = \varphi_i(g_i^\circ) \in \pi_i$ is then the corresponding element of $\pi_1(U)$ in question in the statement (less precise, since it only speaks of a conjugacy class). It is clear that σ_i (operating trivial^{ly} on T_i, and on π_i by transport of structure) commutes with the injective homomorphism φ_i, hence [d1] φ_i induces [d2] $T_i \longrightarrow \pi_i^{\sigma_i}$. I say that this is in fact an isomorphism

$$(14) \qquad \varphi_i : T_i \xrightarrow{\sim} \pi_i^{\sigma_i}$$

– it remains to prove surjectivity. But if $\gamma \in \pi_i^{\sigma_i}$, then $\tilde{x}\gamma \in \widetilde{U}_i^{\sigma_i}$, hence $\tilde{x}\gamma \in \varphi_i(\widetilde{Z}_i)$ which means that $\tilde{x}\gamma = \tilde{x}\varphi_i(g)$ [d3] for $g \in T_i$ hence $\gamma \in \operatorname{Im}\varphi_i$, q.e.d.

Corollary 1 Let $\sigma_i \in \mathcal{T}_g$ $(0 \leq i \leq g)$, corresponding to an anti-involution σ_i of X_g such that $\operatorname{card}\pi_0(X_g^{\sigma_i}) = i$. Then a) There are exactly i Π_g [i1]-conju- and X_g/σ nonori-entable....

[p. 227] I feel like constructing a geometric[i1] figure where one can bring out simultaneously topological anti-involutions which [d1] give rise to the $\sigma_i \in \mathcal{T}_g^\natural | \mathcal{T}_g^\sharp$ (up to conjugation..), and to the various $u_i \in \mathcal{G}_g$[i2] associated with a σ_i (which will then be easy, by the general recipe). We know that $\sigma_i \in \mathcal{T}_g$[i3] is obtained by regarding an X_g as the oriented double of a $Y = Y_{g-i,i}$, thus starting from the [d3] real projective plane Y_0, by making g holes in it, [d6] one [d7i4] fills $g - i$ back in with Möbius bands, leaving the i other holes as they are. Let D_j $(1 \leq j \leq g)$ be the disjoint closed disks corresponding to the "holes, thus [d8]

$$V_{0,j} = Y_0 \setminus \bigcup_j \mathring{D}_j \tag{17}$$

is a manifold with boundary (nonorientable), contained both in Y_0, and in $Y = Y_{g-i,i}$, and even coinciding with Y at the points of

$$\partial Y = \bigcup_{g-i+1 \leq j \leq g} \partial D_j .$$

[d9] Let X_0 be the oriented sphere which covers Y_0,

[scan 452]

In summary:

Proposition We can obtain (for $0 \leq i \leq g$ fixed) the pairs (X_g, σ_i), up to homeomorphisms, by taking the [d1] oriented Euclidean[i1] sphere X_0, with its standard antipodism τ, by taking a set of $2g$ disks D'_j $(j \in J)$[i2] mutually disjoint, stable under τ, and a subset $I' \subset J/\tau = I$ (I of cardinality g) with card $I' = i$, and by proceeding as follows: for every $j \in I$, let $\Delta_j = D'_j \cup D''_j$ be the union of the two[i3] corresponding disks, and $S_j = \partial\Delta_j/\tau$, so that S_j is a circle, let

introduce it later

$$T_j = S_j \times \mathbb{I}^{\xi_j}$$

(where $\mathbf{I}|\mathbb{I} = [-1, +1]$), $\varepsilon_j = \{j' \in J | \mathbf{I} \mid j' \text{ over } i\} \simeq$ set of orientations of S_j[i4], $\mathbf{I}^{\varepsilon_j}|\mathbb{I}^{\varepsilon_j}$ twisted by ε_j, so that we have a canonical homeomorphism

$$\partial T_j \simeq \partial\Delta_j. \tag{25}$$

i.e. $\partial T \simeq \partial V_0$ [d2] reverses it[i5]

m539

Marginal note. [m539] so that $X_g = V_0|U_0 \amalg_{\partial\Delta} T$ (where $\Delta = \coprod_1^g \Delta_j$, $T = \coprod_1^g T_j$) is oriented|oriented

m540

Marginal note. [m540] N.B. T_j is canonically oriented and the isomorphism (25) respects as it should|should the orientation

This being understood, the antipodism τ induces on each $\partial T_i|\partial T_j \simeq S_j \times \varepsilon_j$[i6], [d3]the[i7] canonical[i8] anti-involution [d4] coming from this[i9] expression of ∂T_i, which interchanges the two connected components.

For every|$\forall$[i10] $j \in I|I'$, we extend $\dot{\tau}|\partial T_j$ to T_j as two anti-involutions $\dot{\tau}_j$, $\dot{\tau}'_j$[i11] of T_j, [d5] [d6] in such a way that

[scan 453]

[p. 229]

a) [d1], $\dot\tau_j$ has no fixed points

b) [d2], $\dot\tau'_j$ has a set of fixed points homeomorphic to S_j by the projection $T_j^{\dot\tau_j|\dot\tau'_j} \longrightarrow S_j$ (cf. below } for particular and explicit choices }. — we see|will see that we can even|= suppose $T_j^{\dot\tau_j|\dot\tau'_j} = S_j \times \{0\}$).

Let, for every subset $I' \subset I$, $\tau_{I'}$ be the anti-involution of $X_g = V_0 \amalg_{\partial T} T$ (where $V_0 = X_0 \setminus \bigcup_{j\in J} D'_j$) which coincides with τ on V_0, with τ'_j on T_j for $j \in I'$, with $\tau_j^0|\dot\tau_j$ for $j \in I \setminus I'$. Then we have

$$X_g^{(\tau_{I'})} = \bigcup_{j\in I'} (S_j \times \{0\}) \tag{26}$$

so if $\operatorname{Card} I' = i$ $(0 \le i \le g)$, then $\tau_{I'}$ is a σ_i.

Choice of the $\dot\tau_j$, $\dot\tau'_j$. We choose an isomorphism $S_j \simeq \mathbb{U}|\mathbf{U} \overset{\text{df}}{=} \{z \in \mathbb{C} \mid |z| = 1\}$, whence an orientation of S_j, and a bijection $\varepsilon_j \simeq \{\pm 1\}$, whence $\mathbf{I}^{\varepsilon_j}|\mathbb{I}^{\varepsilon_j} \simeq I|\mathbf{I} = [-1,+1]^{\text{i1}}$ and we take;

$$\begin{cases} \dot\tau_{j|g}(z,t) = (-z\exp \pi i t, -t) \\ \dot\tau'_{j|g}(z,t) = (z,-t) \end{cases} \tag{27}$$

m541

Marginal note. m541 N.B. For the definition of|of the $\dot\tau'_j$, we do not need the choice of an isomorphism $S_j \simeq \mathbb{U}|\mathbf{U}$ (27)

d5 We do have $\dot\tau^2 = \mathrm{id}$, $\dot\tau'^2 = \mathrm{id}$

$$\dot\tau|\partial T = \dot\tau'|\partial T = \tau|\partial T,$$

Moreover

140-2-s453-D005 *deletion. Manuscript:* We do have $\dot\tau^2$
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 454]

We note that

$$(\dot\tau'\dot\tau)^2 = \dot\tau'\dot\tau\dot\tau'\dot\tau = ((z,t) \longmapsto (z \exp 2i\pi t, t))$$

this is not the identity map — the set of its fixed points is equal to: d1 the set of (z,t) such that $t \in \{-1, 0, +1\}$ — i.e.

$$T_j^{(\dot\tau'_j\dot\tau_j)^2} = S_j \times [\partial\mathbf{I}|\mathbb{I}^{\varepsilon_j} \cup \{0\}] \tag{28}$$

d2

d3

Let $\rho_j =$.

$$\dot\rho_j = \dot\tau'_j\dot\tau_j \qquad [(z,t) \longmapsto (-z \exp \pi i t, t)] \tag{29}$$

— this is an automorphism of T_j which is the identity on ∂T_j. d5 For every subset I' of $I = J/\tau$, let

(30) $\rho_{I'}$ be the automorphism of X_g which is the identity on $V_0 = X_g - \bigcup_{j\in I-I'} T_j$, and which is ρ_j on T_j for $j \in I'$.

m542

Marginal note. m542 Setting $\rho_j = \rho_{\{j\}}$, we will simply have $\rho_J = \prod_{j\in J} \rho_j$. Unless I am mistaken, ρ_j generates the group $S\Gamma^{!+}(T_j)|S\Gamma^{!*}(T_j) \simeq \mathbb{Z}$, so the ρ_j generate a group $\simeq \mathbb{Z}^I$. (oriented on[illeg. 1])i1

We will therefore have

$$\begin{cases} \tau_{I'}\tau_{I''} = \rho_{I'_0}\rho_{I''_0}^{-1} \end{cases} \tag{32}$$

N.B. We have $\rho_j = \tau_{\{j\}}\tau_\emptyset$.

d11 where d12 d13 $I'_0 = I' \setminus I' \cap I''$, $I''_0 = I'' \setminus I' \cap I''$.i2

on the other hand we will obviously have

$$[\rho_J, \rho_K] = 1 \qquad \text{for } J, K \subset I. \tag{33}$$

Remark. Instead of an isomorphism $S_j \simeq \mathbb{U}$, suppose rather that we are given on

chooses in each D'_j a "center" a'_j, in a way compatible with the involution, then the choice of the $a'_j \in \mathrm{Int}(D'_j)$ defines a torsor structure on $\partial D'^*_j$, and these structures are invariant under conformal transformations which respect the set of points a'_j.

m544

Marginal note. [m544] N.B. We no longer assume necessarily that D_j is a circle, only that ∂D_j not too [d1] wild. If ∂D_j is a circle, this definition coincides with the preceding one iff $a_j|a'_j$ is the center of the|of this circle…

Re-N.B. To define τ_j on T_j, considerably less data suffice than a topological torsor structure on T_j. Writing for $(z,t) \in S_j \times \mathbf{I}|\mathbb{I}^{\varepsilon_j}$[i1]

$$\tau_j(z,t) = (u_t(z), -t) \tag{37}$$

where $u_t : S_j \xrightarrow{\sim} S_j$ is a homeomorphism depending continuously on t, writing that $\tau_j|\partial T_j = \tau|\partial T_j$, we find the condition

$$\text{a)} \quad u_t = \mathrm{id} \quad \text{if } t \in \partial\mathbf{I}|\mathbb{I}^{\varepsilon_j} \simeq \varepsilon_j$$

m545

Marginal note. m545 this is written, if S_j is oriented, $u_1 = u_{-1} = 0$.

writing that $\tau_j^2 = \mathrm{id}$ we find the condition

$$\text{b)} \quad u_{-t} = u_t^{-1} \qquad (t \in \mathbf{I}|\mathbb{I}^{\varepsilon_j})$$

and writing that $T_j^{\tau_j} = \emptyset$ we find

$$\text{c)} \quad u_0 \text{ without fixed points.}$$

If an orientation is chosen, the $t \longmapsto u_t$ satisfying a) b) c) correspond to the maps $[0,1] \xrightarrow{t \mapsto u_t} \mathrm{Aut}(S_j|S_1)$ such that $u_1 = \mathrm{id}$, u_0 without fixed point d4and of order 2i3. (The case considered above is the one where $t|* \longmapsto u_{1-t}$ comes from a continuous representation $\mathbb{R} \longrightarrow \mathrm{Aut}(S_j|S_1)$…)

[scan 457]

[p. 231]

Remarks We may set ourselves the task of determining the structure of all anti-involutions τi1 on an oriented i2 cylinder $T \simeq S \times \mathbf{I}^{\varepsilon}|\mathbb{I}^{\varepsilon}$ ($\varepsilon = \mathrm{Or}(S)$) which d1 have no fixed point on the boundary — which already implies that d2τi3 permutes|permute the two connected components of the boundary. More generally, the anti-involutions τi4 of an oriented d3surfacei5 with boundary X, having no fixed point on ∂X, correspond to manifolds with boundary Y equipped with a subset both open and closed $(\partial Y)'$ of ∂Y — by associating to such a $(Y, (\partial Y)')$ its oriented "doubling" relative to $(\partial Y)'$ — to X, σ corresponding $(X/\sigma, \mathrm{Im}\, X^{\sigma} \longrightarrow X/\sigma)$. If X is connected, compact,i6 Y is compact,i7 nonorientable, suppose that its type (γ, j), d4 and d5 let $0 \leq i \leq j$, and,i8

$i|i' = \operatorname{card}(\pi_0((\partial Y)'))$= card $\pi_0(X^\sigma)$[i9]. Thus $\chi(Y) = 1 - (\gamma + j)$, and we know|see at once that [d6] (for the χ of a circle is zero)

$$\chi(X) = \chi_! \left(\underbrace{X \setminus (X \mid \partial Y)}_{X|\mathrm{Int}(Y)} \right)$$
$$= 2\chi_!(\operatorname{Int} Y) = 2\chi(Y) = 2(1 - (\gamma + j))$$

thus if X is of [d7]type[i10] (g, ν), we will have $\chi(X) = 2 - 2g-|+\nu$[i11]

$$2 - 2g-|+\nu = 2(1 - (\gamma + j))$$

i.e.

$$g + \frac{\nu}{2} = \gamma + j \tag{38}$$

m546

Marginal note. [m546] not true! If Y orientable of type (γ, j) (same|with $0 \leq i \leq j$) we will have

$$\begin{cases} g + \frac{\nu}{2} = 2\gamma + j - 1 \\ \nu = 2(j - i) \end{cases} \tag{39}$$

i.e. $i = j - \frac{\nu}{2}$ (as in the case opposite)

(this requires that ν be even, which was obvious a priori, since σ must permute the elements of $\pi_0(\partial X)$ among themselves without there[i1] being a fixed point…) [d1] [d2] [d3] [d4] But I forgot to note that ν is determined as a function of $(\gamma, j, i =$ card$((\partial Y)'))$ by[i2] [d5] [d6] [d7]

$$\nu = 2(j - i) \tag{39}$$

i.e. $\underline{i = j - \frac{\nu}{2}}$.

Thus here (for $g = 0, \nu = 2$) we must look for (γ, j, i), with $\gamma \in \mathbb{N},\ 0 \leq i \leq j \in \mathbb{N}$, such that we have $\nu = 2(j - i)$ i.e. $j - i = 1$ i.e. $i = j - 1$, and $\gamma + j = 1$, which gives the only[i4] possibility (since i must be ≥ 0 hence $j \geq 1$)

a) $\gamma = 0,\ j = 1,\ i = 0$:|.
[d8]

Case a) corresponds to the case where [d9] $T^\sigma = \emptyset$, [d10] is obtained from the real projective plane by making [d11]one[i5] hole|holes in it, with boundary (hence Möbius strip)[i6] and by [d12]taking the [d13] oriented doubling[i7]. [d14]

The case where $T^\sigma \neq \emptyset$ will necessarily give a quotient Y[i8] that is oriented, we must have for its type (γ, j) (since $j \geq 1$), the sole case:

which will be close to a braid group, and probably computable without much trouble — and by putting it[i1] together with the group generated by the preceding operators, we will perhaps find a start for generating for example $\mathcal{T}_g|\Pi_g$ by generators (anti-involutive?)[i2] and relations.

Let us consider the [d1]group G of $A_g = \operatorname{Aut} X_g$ generated by the [d2]$\tau_{I'}$[i3] ($I' \in I$), [d3] Let $\mathcal{H}$ [d4] be the subgroup generated by the ρ_j ($j \in I$). We have

$$\begin{aligned}\tau_{I'}\rho_j\tau_{I'} &= \tau_{I'}(\tau_{\{j\}}\tau_\emptyset)\tau_{I'}\\ &= (\tau_{I'}\tau_{\{j\}})\underbrace{(\tau_\emptyset\tau_{I'})}_{\rho_{I'}} \in \mathcal{H}\end{aligned}$$

by formula (31)|(32), so $\mathcal{H}$ is an invariant subgroup.

Formulas (32) show that $G/\mathcal{H}$ is a commutative group, [d7]and even that it is isomorphic to[i4] ± 1 by the orientation character (all the $\tau_{I'}$ are equal modulo $\mathcal{H}$).

Scans 461–470

[scan 461]

[p. 233]

Let us consider as reference element of $\mathcal{H}^-$ the element

$$(40) \qquad \tau = \tau_\emptyset \qquad \text{(anti-involution without fixed points of } X_g)$$

we then find by (32)[i1] that for $I' \subset I$

$$(41) \qquad \tau_{I'} = \rho_{I'}\tau = \left(\prod_{j\in I'} \rho_j\right) \cdot \tau$$

m548

Marginal note. [m548] we see at once, since $\tau^2 = 1$, $\tau_{I'}^2 = 1$, that $\tau_{I'} = \tau_{I'}^{-1} = \tau\rho_{I'}^{-1}$ hence $\tau\rho_{I'}\tau = \rho_{I'}^{-1}$ which is (42)|which ⇒ (42)

moreover we will have, for $j|i \in I$[i2]

$$\tau\rho_i\tau = \tau_\emptyset\left(\tau_{\{j|i\}}\tau_{\{\emptyset\}}\right)\tau_{\{0\}} = \tau_\emptyset\tau_{\{j\}} = \rho_j^{-1}$$

$$(42) \qquad \tau\rho_i\tau^{-1} = \rho_i^{-1}.$$

Thus $\mathcal{G}$ appears as the semidirect product of $\mathcal{H} \simeq \mathbb{Z}^I$, and of [d2] $\{\pm 1\} \simeq \{1, \tau\}$ operating on it by the symmetry $\rho \longmapsto \rho^{-1}$. So for every $\rho \in \mathcal{H}$, †[d3] we have $(\tau\rho)^2 = 1$, i.e. for every $\sigma \in \mathcal{H}^{-1}$, σ [d4] is an anti-involution ! Since σ agrees with τ on $V_0 = X_g - \bigcup_{j|i\in I} \mathrm{Int}(T_j)$, we see that the set of fixed points of σ is contained in $\bigcup_{i\in I} \mathrm{Int}(T_i)$, and to calculate the index of σ, i.e. $\mathrm{card}\,\pi_0(X_g^\sigma)$, it suffices to take the sum of the 460

[scan 462]

indices in the T_j. Now in T_j, we have (29)[i1] $\rho_j(z,t) = (-z\exp\pi it, t)$, and by induction

$$(43) \qquad \rho_j^{n_j}(z,t) = \left((-1)^{n_j} z \exp n_j\pi it, t\right)$$

hence

$$(44) \qquad \tau\rho_j^{n_j}(z,t) = \big((-1)^{n_j+1} z \exp(n_j+1)\pi i t, -t\big)$$

and [d1] $(z,t)\in T_j$[i2] is a fixed point of $z|\tau\rho_j^{n_j}$ iff|without $t=0$, [d2] and n_j is odd, hence

$$(45) \qquad T_j^{\tau\rho_j^{n_j}} = \begin{cases} \emptyset & \text{if } n_j \text{ even} \\ S_j \times \{0\} & \text{if } n_j \text{ odd} \end{cases}$$

hence

$$(\tau\rho)(\tau\rho')(\tau\rho)^{-1} = \underset{[\text{illeg. 1}]}{\tau\rho} \underbrace{\tau\rho'\rho^{-1}\tau}_{\rho\rho'^{-1}} = \tau\rho^2\rho'^{-1} = \tau\rho''$$

as soon as $\rho^2 = \rho'\rho''$, i.e.|i.e. [illeg. 3] $\tau\rho'$ is conjugate [illeg. 1] $\tau\rho''$ in $\mathcal{G}$, as soon as $\rho'\rho'' \in \mathcal{H}^2$
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 463]

[p. 234]

But if $\tau\rho', \tau\rho'' \in \mathcal{G}^-$, $(\rho', \rho'' \in \mathcal{H})$, and if $\rho \in \mathcal{H}$, the relation

$$\rho(\tau\rho')\rho^{-1} = \tau\rho''$$

is equivalent to

$$\underbrace{\tau\rho\tau}_{\rho^{-1}}\rho'\rho^{-1} = \rho'' \qquad \text{i.e.} \qquad \rho^2 = \rho'\rho''^{-1}$$

hence $\tau\rho'$ and $\tau\rho''$ are conjugate by an element of $\mathcal{H}$ iff|without $\rho'\rho''^{-1} \in \mathcal{H}^2$ – which makes the preceding observation more precise…

The way richest in simple symmetries for arranging the $2g$ antipodal holes D_j seems to me to be the following. We [d1] consider the Euclidean sphere, with the action of the dihedral group $\mathbb{D}_{2g}|\mathbf{D}_{2g}$ – for example, when it is the Riemann sphere that is considered as Riemannian, by the choice of the antipodism as being

$$(47) \qquad \tau z = -\frac{1}{\bar{z}}$$

we take the standard action of the dihedral group (with the points $0, \infty$ as poles, and the unit circle $\mathbb{U} = \{z \in \mathbb{C} : |z| = 1\}$ as equator), [d2] by writing $\mathbb{D}_n|\mathbf{D}_n$ as $\subset \mathrm{O}(2, \mathbb{R})$, as a $\frac{1}{2}$ direct product of [d4]$\{\pm 1\}$[i1] by $\mu_n(\mathbb{C}) = \mu_n$, the pair (ζ, α) $(\zeta \in \mu_n, \alpha \in \{\pm 1\})$ operating by

$$(48) \qquad u_{\zeta,\alpha}(z) = \zeta z^\alpha$$

[scan 464]

We can moreover enlarge it to a group $\mathbb{D}_n^\sim = \mathbb{D}_n \times \mathbb{Z}_{/2}$, where the second factor $\mathbb{Z}_{/2}$ is generated by the antipodism (47) (which commutes with $\mathbb{D}_n$ — likewise moreover does the anti-involution $z \longmapsto \frac{1}{\bar{z}}$, which has as its set of fixed points $\mathbb{U}$ and is nothing other than the symmetry with respect to the equator, their composite $z \longmapsto -z$ being the symmetry with respect to the axis of the poles …) hence to consider the transformations

$$u_{\zeta,\alpha,\beta} = \zeta u_{\zeta,\alpha}\tau^\beta \qquad (\zeta \in \mu_n,\ \alpha \in \{\pm 1\},\ \beta \in \mathbb{Z}_{/2})$$

hence

$$u_{\zeta,\alpha,\beta}z = \begin{cases} u_{\zeta,\alpha}(z) = \zeta z^{\alpha} & \text{si } \beta = 0 \\ u_{\zeta,\alpha}(-\frac{1}{\bar{z}}) = -\zeta \bar{z}^{-\alpha} & \text{si } \beta = 1 \end{cases},$$

but we will remember that τ reverses the orientation, hence [d2]is to be[i1] [d3]handled[i2] with caution as regards "transport of structure" in the present situation.

Here $n = 2g$, $\mathbb{D}_{2g|n}$ is of order $4g$, and $\mathbb{D}_n^{\sim}$ of order $8g$. We take on the equator an orbit $\mathcal{J}|\mathbb{J}$, of $\mu_n = \mu_{2g}$, for example the|here precisely [d4] (μ_{2g} the set of $2g$th roots of unity[i3] itself, viewed[d5] as a subset of the sphere) as the set of "centers" of the disks D'_i. We choose a disk D'_0 around the point|point P_0 (small enough for what is to follow), and we take the transforms|transforms of D'_0 by the $\zeta \in \mu_n$.

m553

Marginal note. [m553] it is simply necessary that D'_0 not meet $\zeta_0|\zeta D'_0$, where $\zeta = \exp\frac{2i\pi}{2g}$

[p. 235]

These choices having been made, the surface X_g is determined without ambiguity|ambiguity, and the group $\mathbb{D}_{2g}$ operates on it by transport of structure, permuting the g cylinders T_i among themselves, corresponding|corresponding to the elements of $\mathcal{J}|\mathbb{J}/\tau =^{i1} \mathcal{J}|\mathbb{J}/\{\pm 1\}$ i.e. to the pairs of antipodal elements of $S|\mathcal{J}$, i.e. to the "diagonals" of the polygon with 2μ sides which they [d1]determine[i2] on the equator. The group $\mathbb{D}_{2g}$ normalizes [d2] the group $\mathcal{G}$, to be precise we will have, for $u \in \mathbb{D}_{2g}$

$$u\tau_{I'}u^{-1} = \tau_{u(I')} \tag{49}$$

for $I' \subset I = \mathcal{J}|\mathbb{J}/\tau$, taking into account the operation of $\mathbb{D}_{2g}$ on I. We will thus have in particular, denoting by $\tau_g = \tau_{\emptyset}$[i3] the extension of the antipodism of the sphere X_0 (or rather of

$\tau|V_0$) to an antipodism without fixed points of X_g, denoted τ previously:

$$u\tau_g u^{-1} = \tau_g \qquad \text{i.e. } \tau_g \text{ commutes with the action of } \mathbb{D}_n \tag{50}$$

$$u\rho_j u^{-1} = \rho_{u(j)}$$

We can therefore say that $\mathbb{D}_{2g}$ operates on $\mathcal{G}$, whence a $\frac{1}{2}$-direct product $\mathbb{D}_{2g}.\mathcal{G}$, which therefore operates on X_g. As for the question of extending likewise the action on X_0,[i4] of $\mathbb{D}_{2g}^{\sim}$ [d5] as a whole to an action on X_g, 464

[scan 466]

this has been done without warning, to τ_{X_0} corresponding naturally $\tau_{X_g} = \tau_g$, which indeed has the good taste to commute with the action of $\mathbb{D}_{2g}$. [It might seem more natural, it is true, in a spirit of "transport of structure (in spite of and against everything?)", to associate to τ_{X_0} the operation $\tau_I$given|given by (27)[i1], which on each T_j would be equal to τ'_j (and on V_0, of course, coincides with τ_{X_0}), $\tau'_j(z,t) = (z,-t)$, [d1] the set of fixed points of τ_I^2 being formed of the g middle circles $S_j \times \{0\}$ of the g tubes T_j. We will have by (41) $\tau_I = \rho_I \tau_g$, hence τ_I commutes also with $\mathbb{D}_n$, since τ and $\rho_I = \prod_{i\in I} \rho_i$ commute with it. But it does|to me does not seem important for the moment which convention we adopt]

We can therefore also say that the group $\mathbb{D}_{2g}^{\sim}$ operates on $\mathcal{H}$ — this operation extending that of τ_g [d2], now identified with an element of $\mathbb{D}_{2g}^{\sim}$, i.e. with the antipodism in $\mathbb{D}_{2g}^{\sim}$ — and the $\frac{1}{2}$ direct product

$$\mathbb{D}_{2g}^{\sim}.\mathcal{H} \supset \mathcal{G} = \{1, \tau_g\}.\mathcal{H} \tag{51}$$

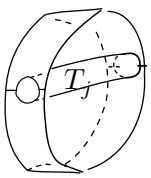
[p. 236]

operates on X_g.

One should now, along these lines:



1) Make explicit the outer action of this $\frac{1}{2}$ direct product on the fundamental group π_g, with very special attention to the action of the group $(\mathbb{Z}/2\mathbb{Z})^3 \subset \mathbb{D}_{2g}^{\sim}$ which stabilizes one of the cylinders T_j — which in Euclidean space of dimension 3 is interpreted as the group of changes of sign relative to the|a corresponding orthonormal system of axes.

2) Extend the action on ${\pi_g}^{i1}$ of the (more or less) "special" Teichmüller group of each of the T_j, to the action of an analogous group of a larger set obtained by adding to it a "strip" L^{i2} (whence a torus with 1 hole, and its special Teichmüller group, which come in naturally*) or even|see the still larger set obtained by also putting in the antipodal strip L' (this set presents itself as a cylinder $(L \cup L')$, or "culvert", in which one would have put a tube (T_j) crosswise, and has the topological structure of a torus with two holes.

m558

Marginal note. m558 * This is essentially an $\mathrm{SL}(2,\mathbb{Z})$ — rather a remarkable central extension of $\mathrm{SL}(2,\mathbb{Z})$ by $\mathbb{Z}$, which recalls that of $\mathrm{SL}(2,\mathbb{R})$ by $\mathbb{Z}$… (universal covering of $\mathrm{SL}(2,\mathbb{R})$)

[scan 468]

It is possible that it will be necessary to look closely at this last one, to study the relations among the[i1] elements of $\mathcal{T}_g$ coming from the preceding sets… An amusing job will be to manage to write down the generators of the group π_g, and above all the famous relation, in a relative geometric arrangement of the "handles", which is a "mixed" arrangement — and no longer nicely in single file!
d1

While waiting to get to the heart of the structure of the Teichmüller group in this way, I will already try to describe generators and relations for the interesting subgroup we have just written down, $\mathbb{D}_{2g}^{\sim} \cdot H$. I will take the everlasting generators $\varepsilon_0, \varepsilon_1$ of $\mathbb{D}_{2g}$

$$\varepsilon_0^2 = \varepsilon_1^2 = 1, \qquad (\varepsilon_0\varepsilon_1)^{2g} = 1$$

and adjoin to them $\tau = \tau_g$, and [d2] $\rho_0\tau = \tau'$ ($\rho_0 = \rho_{j_0}$, j_0 marked point of $I = J/\tau$) satisfying

$$\tau^2 = \tau'^2 = 1,$$

$$(\tau\varepsilon_0)^2 = (\tau\varepsilon_1)^2 = 1$$

$$(\varepsilon_1\tau')^2 = 1 \qquad \varepsilon_1 \text{ commutes with } \tau'$$

m560

Marginal note. [m560] N.B. ε_0 moves the vertex of the frame, ε_1 the edge and not the vertex, hence $\varepsilon_1(j_0) = j_0$
m561

Marginal note. [m561] express the commutation of τ [d5] with $\varepsilon_0, \varepsilon_1$

[scan 469]

[p. 237]

$$((\varepsilon_0\varepsilon_1)^g\tau')^2 = 1$$

m563

Marginal note. m563 (the involution $(\varepsilon_0\varepsilon_1)^g$ commutes with τ')

unless I am mistaken, that gives a set of generators and relations for $\mathbb{D}^{\sim}_{2g} \cdot \mathcal{H}$ — in summary $\varepsilon_0, \varepsilon_1, \tau, \tau'$

$$(52) \quad \begin{cases} \varepsilon_0^2 = \varepsilon_1^2 = \tau^2 = \tau'^2 = 1 \\ (\tau\varepsilon_0)^2 = (\tau\varepsilon_1)^2 = (\tau'\varepsilon_1)^2 = 1 \\ (\varepsilon_0\varepsilon_1)^{2g} = 1 \\ (\tau'(\varepsilon_0\varepsilon_1)^g)^2 = 1 \end{cases}$$

This is perhaps not a very clever choice of generators, in the sense that $\varepsilon_0, \varepsilon_1$, are not at all on the same footing as τ, τ' — they are not anti-involutions. It would be better to take $\varepsilon'_0 = \tau\varepsilon_0$, $\varepsilon'_1 = \tau\varepsilon_1$ so as to obtain

$$(52\text{bis}) \quad \begin{cases} \varepsilon_0'^2 = \varepsilon_1'^2 = \tau^2 = \tau'^2 = 1 \\ (\tau\varepsilon'_0)^2 = (\tau\varepsilon'_1)^2 = (\tau'(\tau\varepsilon'_1))^2 = 1 \\ (\varepsilon'_0\varepsilon'_1)^{2g} = 1 \\ (\tau'(\varepsilon'_0\varepsilon'_1)^g)^2 = 1 \end{cases}$$

these are essentially "the same" relations except for the last one in the second line.

Perhaps this little game with the tiny group $\mathbb{D}^{\sim}_n$ operating on $\mathcal{H}$ is a bit of a diversion — the group $\mathcal{H} \simeq \mathbb{Z}^g$ in $\mathcal{T}_g$ strongly suggests the situation 468

[scan 470]

of a maximal torus in a $\frac{1}{2}$ simple group, one really wants to have|see an intrinsic characterization of it in $\mathcal{T}_g$ — or in $\mathcal{S}_g|\mathcal{G}_g|\mathcal{C}_g$, which is possible since d1 as a group of actual|actual topological transformations, it leaves fixed the points of $V_0 \subset X_g$ — for example the two poles, which one can take as base|base points to construct universal coverings and fundamental|fundamental groups. These are perhaps the maximal free-abelian|abelian subgroups.

One would like to study the normalizer — is it exactly what comes from the automorphisms of $X_g - \bigcup \mathring{T}_i \simeq V_0$?

do the $\mathrm{SL}(2, \mathbb{Z}_j)$ associated with the "strips" through the tube T_j i1 play a role analogous to that of the groups $\mathrm{SL}(2, K)$ or $\mathrm{GP}(1, k)|\mathrm{GL}(1, k)$ "of rank 1" in the theory of reductive algebraic groups? If Jean does not|me "bite" 469

[scan 473]

a discretification π_0 of π, hence π'_0 of π', we then find

$$\widehat{\widehat{\mathcal{G}}}(\pi_0) \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi'_0)$$

and we have

① The homomorphism $\widehat{\widehat{\mathcal{G}}}(\pi_0) \longrightarrow \widehat{\widehat{\mathcal{G}}}(\pi'_0)$ sends $\mathcal{M}(\pi_0)$ into $\mathcal{M}(\pi'_0)$

we will therefore have a diagram (a variant|relative of the one in § 28)

(1)
$$\begin{array}{ccccc} \widehat{\mathcal{G}}^{+}(\pi_0) & \hookleftarrow & \mathcal{M}(\pi_0) & \hookleftarrow & \widehat{\widehat{\mathcal{G}}}(\pi_0) \\ \downarrow & & \downarrow & & \downarrow \\ \widehat{\mathcal{G}}^{+}(\pi'_0) & \hookleftarrow & \mathcal{M}^{*|\sharp}(\pi'_0) & \hookleftarrow & \widehat{\widehat{\mathcal{G}}}(\pi'_0) \end{array}$$

which [d1] implies that a discretification π_1 on π which gives the same oriented prediscretification as π_0 (resp. the same arithmetization) defines a discretification[i1] π'_1 of π' which gives the same oriented prediscretification (resp. the same arithmetization) as π'_0. Thus we do have $P^{+}(\pi) \longrightarrow P^{+}(\pi')$, $A(\pi) \longrightarrow A(\pi')$, we still have to express injectivity, which amounts to the relations

$$(2) \quad \widehat{\mathcal{G}}^{+}(\pi_0) = \widehat{\mathcal{G}}^{+}(\pi'_0) \cap \widehat{\widehat{\mathcal{G}}}(\pi_0), \qquad \mathcal{M}(\pi_0) = \mathcal{M}(\pi'_0) \cap \widehat{\widehat{\mathcal{G}}}(\pi_0)$$

[scan 475]

"potential curves", we find a connected groupoid (pointed by the $\hat{\pi}_{g,\nu}$, for example, [d1] which are canonically isomorphic there), whose outer π_1 is the common value of the $\mathbb{\Gamma}_{g*} = \mathbb{\Gamma}_{g,\nu}$.

To find an the isomorphism canonical[i1] between $\mathbb{\Gamma}_{g,\nu}$ and $\mathbb{\Gamma}_{g',\nu'}$, we choose a [d2] correspondence between[i2] a $\pi_{g,\nu}$ and $\pi_{g',\nu'}$, for example by regarding [d3] both of them (passing if need be: from g,ν to $g,\tilde{\nu}$ with $\tilde{\nu} \geq \nu$, and likewise for g',ν' to $(g',\tilde{\nu}')$ with $\tilde{\nu}' \geq \nu'$) as finite subgroups of the same $\pi_{0,3}$ and whence

$$\mathbb{\Gamma}_{0,3} \xrightarrow{\sim} \Gamma_{g,\tilde{\nu}}, \qquad \Gamma_{0,3} \xrightarrow{\sim} \Gamma_{g',\tilde{\nu}'}.$$

We would now like to see what, in the preceding yoga, is independent of any conjecture. For example, the fact that the surjective homomorphisms canonical[i3] $\mathbb{\Gamma}_{g,\nu} \longrightarrow \mathbb{\Gamma}_{g,\nu'}$ (g the same, ν' constant) is not established.

However, if we knew that in the situation of (π,π') with π' characteristically invariant we had

$$\widehat{\widehat{\mathcal{T}}}(\pi'_0) \cap \widehat{\mathcal{G}}^{+}(\pi_0) = \widehat{\mathcal{G}}^{+}(\pi_0)$$

[p. 241]

(which is a statement of a relatively innocuous nature about profinite groups with loops) we would conclude the bijectivity of $\mathbb{\Gamma}_{\pi_0} \longrightarrow \mathbb{\Gamma}_{\pi'_0}$ in this situation, and we would conclude from this that the kernel of $\mathbb{\Gamma}_{\mathbb{Q}} \longrightarrow \mathbb{\Gamma}_{0,3}$ [d1] maps trivially into the $\mathbb{\Gamma}_{g,\nu}$ for $\forall \nu$ – i.e. that it maps into the $\mathbb{\Gamma}_{g,\nu}$ through the intermediary of $\mathbb{\Gamma}_{0,3}$ – and that moreover $\mathbb{\Gamma}_{0,3} \longrightarrow \Gamma_{g,\nu}$ is [d2] an isomorphism for $\forall(g,\nu)$[i1] with ν sufficiently large – it suffices that the surface of type (g,ν) [d3] (or of type (g,ν') with a $\nu' \leq \nu$) can be obtained as an étale covering of $X_{0,3}$, i.e. that $\pi_{g,\nu'}$ is realized (with its structure of loops)[i2] as a subgroup|subgroup [d4] of finite index[i3] [d5] of $\pi_{0,3}$. Then, [d6] considering[i4] a $\pi'' \simeq | \sim\pi_{g'',\nu''}$[i5] $\subset | \in\pi_{g,\nu'}$ of finite index and characteristic in $\pi_{0,3}$, we will have

commutative diagram.

whence our assertion $\Gamma_{0,3} \xrightarrow{\sim} \Gamma_{g,\nu'}$, and a fortiori the surjective homomorphism $\Gamma_{0,3} \longrightarrow \Gamma_{g,\nu}$ which factors it $(\nu \geq \nu')^{\text{i1}}$ is bijective. Let us note for example that the $\Gamma_{0,\nu} \longrightarrow \Gamma_{0,3}$ $(\nu \geq 3)$ are then bijective. But $^{\text{d1d2i2}}$ note that in any case, we obtain a result for a g, ν only if $\nu \geq 3$ – so this says nothing about the possible faithfulness for example of $\Gamma_{0,3} \longrightarrow |-\Gamma_{g,0} = \Gamma_g$ $(g \geq 2)$ or $\Gamma_{0,3} \longrightarrow \Gamma_{1,1} = \Gamma_1$.
m567

[p. 242]

ν to ν' (i.e. making holes to find U'[i1]) we may suppose that U' is an étale covering of †[d1] $(U_{0,3})_K$. [m568]

Marginal note. [m568] we put $\pi' = \pi_1(U'_{\overline{\mathbb{Q}}_0})$ $\pi = \pi_1(U_{\overline{\mathbb{Q}}})$

[d2] [d3] Then let $\Theta|\Theta'$ be the kernel of

$$\begin{array}{ccc} \Gamma'|\Gamma & \longrightarrow & \mathbb{\Gamma}_{0,3} \\ \cap & & \\ \mathbb{\Gamma}_{\mathbb{Q}} & & \end{array}$$

, it therefore operates [d4] inner automorphisms|automorphisms on $\hat{\pi}_{03|0,3}$, so [d5]the[i2] image of $\Theta' = \Gamma' \cap |\wedge \Theta$[i3] in the group of outer automorphisms|automorphisms of $\pi' \subset \hat{\pi}_{0,3}$ is a finite subgroup – a fortiori its image in $\mathbb{\Gamma}_{\pi'}$, and in $\mathcal{N}(\pi)$ and in[i4] $\mathbb{\Gamma}_{\pi}$. The same holds (choosing a base|good point rational over K in U') for the actual operation in|of $\pi_1(U, P)|\pi_1(U', P)$ – for it suffices to apply the preceding result to $U \setminus |-\{P\}$. We also conclude from this that [d6] the kernels of the homomorphisms $\mathbb{\Gamma}_{0,\nu} \longrightarrow \mathbb{\Gamma}_{0,3}$ $(\nu \geq 3)$ are finite. We easily see that for every abelian variety A defined over K, the operation of Θ' on the $\prod_\ell T_\ell(A)$ takes place through a finite quotient group.

It becomes very difficult to imagine, how it †[d7] could happen that $\Theta'|\Theta$ does not operate, in fact, trivially ! I have

[scan 479]

even the impression that I can show thanks to the result of the Russian which Deligne pointed out to me, [d1] that $\Gamma_{\mathbb{Q}} \longrightarrow \Gamma_{0,3}$ is an isomorphism ! That|Tha would mean that the outer actions of $\Gamma_{\mathbb{Q}}$ on π_1's $\simeq \overline{\pi}_{g,\nu}$ [i1] can be interpreted (at least for ν large enough, g being fixed) as splittings of the extension $\mathcal{N}_{g,\nu}$ [i2] of $\Gamma_{g,\nu}$ by $\widehat{\mathcal{T}}_{g,\nu}$ — or of the extension $\mathcal{M}_{g,\nu}$ of $\Gamma_{g,\nu}$ by $\widehat{\mathcal{G}}_{g,\nu}$, when it is a matter of actual actions.

Of course, the essential question which then arises (admitting $\Gamma_{\mathbb{Q}} \simeq \Gamma_{0,3}$) is to characterize $\Gamma_{0,3}$ algebraically, as well as the $\mathcal{N}_{g,\nu}$ — and to give an algebraic description also of the "admissible" splittings — i.e. corresponding really and truly to algebraic curves over algebraic number fields.

that [d1] these are exactly the actions lifting the given|given outer action, which normalize no loop subgroup|subgroups, or again such that $\widehat{\pi}_{0,3}^{\Gamma''+}$ [d2] (1)[i1] (But it is conceivable that more subtle conditions may have to be added to it, involving the Frobenius ...) We may propose to find a description of the outer "admissible" actions, [d3] without having[i2] to pass through admissible actual actions — and to endea-|endevor to give a more or less plausible definition of them. The difficulty of course|course comes from the fact that if Γ'' operates by outer automorphisms on [d4] $\widehat{\pi}_{0,3}$, it does not thereby operate by outer automorphisms on a given open subgroup π'[i3] of $\widehat{\pi}_{0,3}$. But we are going to suppose precisely that such an action exists, [d5] in such a way that[i4] [d6] $\pi' \longrightarrow \widehat{\pi}_{0,3}$ is compatible with the outer actions, and that the action of Γ'' on π is deduced (modulo isomorphism) from

[scan 481]

For this second point, we have an immediate answer (assuming the $\mathcal{N}_{g,\nu}|N_{g,\nu}$ already known). Let a|a (π, a) be of type g, ν, with [d1] a partial[i1] lifting of $\mathbf{\Gamma}_a$ to|a $\Gamma'_{a|\cdot} \hookrightarrow \mathcal{N}_a|N_a$. It will be admissible iff we can find a (π', a') of type (g, ν'), and[i2] an embedding of π' as a subgroup|subgroup of finite index in $\hat{\pi}_{03}$ compatible with a', and an open subgroup Γ Γ''[i3] of $\mathbf{\Gamma}_{03}$, and an admissible[i4] actual action of Γ'' [d2] on $\hat{\pi}_{03}$ which lifts the given outer action, and which leaves π' invariant, so that up to isomorphism, (π, a) and the germ of action of Γ' on it[i5] is deduced from (π', a') by the action of Γ'' on it, by "plugging" a batch of holes (and forgetting an actual action in favor of the outer action)[i6]. One needs in this approach simply to know how to specify algebraically[i7] what is meant by an "admissible" action of $\Gamma'' \subset$[i8] $\mathbf{\Gamma}_{0,3}$ on $\hat{\pi}_{0,3}$ — it being understood that this must correspond to the points of $U_{0,3}$ rational over [d3] the number field defined by Γ''. One can conjecture 480

[p. 244]

this one, by "plugging the holes".

It seems that on the same principle one can give a description of the $\mathcal{N}_{g,\nu}|N_{g,\nu}$ (hence of the $\mathbf{\Gamma}_{g,\nu}$) in terms of $\mathbf{\Gamma}_{0,3}$. Using the transition homomorphisms $\widehat{\widehat{\mathcal{T}}}_{g,\nu} \longrightarrow \widehat{\widehat{\mathcal{T}}}_{g,\nu'}$, it suffices to do so, when g is fixed, for large ν — large enough that there exists an algebraic[i1] curve of type g, ν over $\mathbb{Q}$[i2] which is an étale covering of $U_{0,3}$ over $\mathbb{Q}$.

We therefore consider a corresponding embedding of $\pi_{g,\nu}$ into $\pi_{0,3}$, and decree that if [d1] we can make $\mathrm{ext}^t\ \mathbf{\Gamma}_{0,3}$ operate on $\pi_{g,\nu}$, so that $\pi_{g,\nu} \longrightarrow \pi_{0,3}$ commutes with these outer actions, then the subgroup of $\widehat{\widehat{\mathcal{T}}}_{g,\nu}$ generated by $\widehat{\mathcal{T}}_{g,\nu}$ and $\mathbf{\Gamma}_{0,3}$ is [d2] $\mathcal{N}_{g,\nu}|N_{g,\nu}$. 481

[p. 245] 34. Heuristic profinite description of the category of algebraic curves defined over [d1] finite subextensions K of $\overline{\mathbb{Q}}_0/\mathbb{Q}$ (i.e. of $\mathbb{C}/\mathbb{Q}$).

We restrict ourselves to geometrically[i1] connected curves (for convenience)[i2], anabelian (out of provisional necessity !, cf. below on the way to get rid of this restriction). The datum of a universal covering of [d2] $U_{\overline{\mathbb{Q}}_0}$ defines an extension structure

$$(1) \qquad 1 \longrightarrow \pi \longrightarrow \mathcal{E} \longrightarrow \Gamma^+ \longrightarrow 1 \qquad \text{or}$$

(2) or again we have a homomorphism $\mathcal{E} \longrightarrow \mathbf{\Gamma}$ (image Γ^+ open in $\mathbf{\Gamma}$, kernel called π), where $\Gamma^+ \subset \mathbf{\Gamma}_{\mathbb{Q}} \simeq \mathbf{\Gamma}_{0,3}$ is the open subgroup|subgroup corresponding to K. Giving oneself such an extension (assuming $\mathrm{Centre}(\pi) = 1$) amounts to giving oneself an outer action of Γ' on π. A first question: must one put the loop structure of π in the [d3] data $\mathcal{E}$ of the object (1) (or (2)|(1')) supposed to describe $U\mathcal{E}/K$?

Conjecture It is not worth the trouble – the loop structure of π is the only loop structure invariant under the outer action of Γ^+ (or of $\Gamma^\natural$). The loop subgroups L_i are the maximal subgroupsin π[i3], such that $\mathrm{Norm}_{\mathcal{E}}(L_i) \longrightarrow \Gamma^+$ has as image an open subgroup of $\Gamma^+|\Gamma$. [m571]

Marginal note. [m571] and every subgroup $\neq 1$ of π which has this property is contained in a unique L_i ...

I also presume that every homomorphism [d4]between[i4] extensions $\mathcal{E}$ of Γ^+ by a π, $\mathcal{E}'$ of Γ by a π' ($\mathcal{E}, \mathcal{E}'$ coming from algebraic curves U, U') and such that the image of $\mathcal{E}$ in $\mathcal{E}'$ is open, respects 482

[scan 484]

necessarily the loop structure, and in fact comes from a morphism (unique, as we know) of algebraic curves.

At any rate, if one admits the description of the loop subgroups, it will be clear that the image under u of an L_i will be, either (1), or contained in a unique L'_j ...

This would mean that the functor from algebraic curves over K(morphisms the dominant morphisms)[i1], to profinite outer groups on which Γ operates, would be fully faithful. The functor "extension of the base field" from K to K' corresponds to the functor: restriction of an outer|outer group (or of an extension structure) from Γ to Γ' (open subgroup). The finite étale[i2] coverings of U correspond to $\mathcal{E}$-sets: [$\widetilde{U}$ being chosen]...

To describe the essential image of this functor, we are not reduced to conjectures: we start from the canonical[i3] extension $\mathcal{E}_{03}$ of $\mathbf{\Gamma}_{03} = \mathbf{\Gamma}$ by $\hat{\pi}_{03}$, we take an open[i4] subgroup|subgroup $\mathcal{E}'$ of $\mathcal{E}_{03}$, with image $\Gamma \subset \mathbf{\Gamma}_{03}$, kernel $\pi' \subset \hat{\pi}_{0,3}$, and in the canonical loop structure of $\pi'$of genus g[i5] (induced by that of $\hat{\pi}_{03}$) we take an $I|\overline{I} \subset I(\pi')$such that $2g + \mathrm{Card}(I) \geq 3$[i6], stable under Γ, and[i7] we "plug the holes" at $I(\pi') \setminus I$. Likewise, to describe when 483

[scan 485]

[p. 246|245] an actual action, lifting an admissible outer action, is itself admissible – d1 i.e. can be obtained from an algebraic d2curvei1 U, pointed by a point rational over K. This does not mean for all that, that if U is given by an outer action of Γ on a π, that the conjugacy classes of admissible liftings of this action indeed all come from points of U rational/K. But we see at once that this will be the case, as soon as one admits full faithfulness for isomorphisms

N.B. Even for the automorphisms of $U_{0,3} = \mathbb{P}^1_{\mathbb{Q}} \setminus \{0, 1, \infty\}$, this full faithfulness is not at all clear. One would have to prove that d3 the commutant of $\mathbf{\Gamma}_{0,3}$ in $\widehat{\widehat{\mathcal{T}}}_{0,3}$ is reduced to $\mathfrak{S}_3|\mathcal{S}_3$. The situation is less hopeless, when we give ourselves, along with the structure of a profinitei2 outer group with operators Γ, an arithmetization of π (which supposes that we have made explicit a loop structure) invariant under d4 Γ – thus in $\widehat{\widehat{\mathcal{T}}}(\pi)$ we have at our disposal an $N(\pi)|\mathcal{N}(\pi)$, and $\Gamma \hookrightarrow N(\pi)|\mathcal{N}(\pi)$. From this point of view, fori3 a homomorphism $\pi' \longrightarrow \pi$i4 of outer Γ-groups (arithmetized), it is understood that it is compatible with the arithmetizations, i.e. if π'' is the image of π' in π, 484

we see that the arithmetization of π'' deduced from that of π' by "passage to the quotient", be the one induced by π. d1 In particular, fori1 the automorphisms(outer)i2 of π it is understood that d2 not only do they commute with Γ, but also that they are in $N(\pi)$. (which implies that they are in $\widehat{\mathcal{T}}(\pi)$, for the centralizer in $\mathbf{\Gamma}_\pi$ of every open subgroup of $\mathbf{\Gamma}_\pi$ is (1) !)i3 In the case of

$U_{0,3}$, we have $N_{0,3} \simeq \mathfrak{S}_3 \times \mathbf{\Gamma}_{0,3}$, and we know that the center of $\mathbf{\Gamma}_{03} \simeq \mathbf{\Gamma}$ is trivial – thus we do indeed find that the group of automorphisms of this structure is reduced to|: $\mathfrak{S}_3$!

This point of view is nevertheless probably superfluous – for we presume that for the given outer action of Γ, there is a unique arithmetization invariant under Γ, and that the "admissible"[i4] homomorphisms of the "admissible" outer Γ-groups, as they have been defined previously, automatically respect this arithmetization. If this were not so, one would of course have to introduce the arithmetizations into the structure.

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 487]

[p. 247]

The question arises of finding a more [d1] simplistic[i1] description of the outer actions of a Γ on a π which are "admissible". [d2] Here, we shall start from a π for which we already fix a loop structure and an arithmetization a[i2] (invariant|invariant under Γ), so [d3] that $\Gamma \subset N(\pi)$, $\Gamma \longrightarrow \mathbf{\Gamma}_\pi$ injective with open image, [d4] i.e. Γ corresponds to a partial splitting (or germ of splitting) of [d5]

$$1 \longrightarrow \widehat{\mathcal{T}}(\pi) \longrightarrow N(\pi) \longrightarrow \mathbf{\Gamma}_\pi \longrightarrow 1$$

Let (g, ν) be the type of π; [d6] if $g \geq 1$ the simplest criterion, it is that the "$\Gamma^\natural$-[i3]points" of|of the π' deduced from π by plugging all the holes, be distinct. [d7] (N.B. if $g = 1$, [d8] [d9] by plugging[i4] all the holes we land in an abelian case – but that does not matter). If $g = 0$, [d10] there is no condition for $\alpha|\nu = 3$, and if $\nu > 3$, let us set|setting aside a [d11] subset $I' \subset I(\pi)$ with card $I' = 3$, the condition is that on plugging the holes of|in $I \setminus I'$, the $\Gamma^\natural$-[i5]points of the|of π deduced from the points of $I \setminus I'$ are distinct.

One will note that in this conjectural perspective, in the limiting cases $(g, 0)$ $(g \geq 2)$, $(1, 1)$, $(0, 3)$, we impose no condition a priori[i6] on the liftings.

[scan 488]

This is perhaps very brutal – and it could be that we find liftings which do not correspond to an algebraic curve – i.e. which in fact are not admissible, even if they appear to be.

To understand something of this, it seems to me that we must return to an interpretation of the germs of[i1] splittings called "admissible" of an extension such as

$$\begin{array}{ccccccccc} 1 & \longrightarrow & \widehat{\mathcal{T}}_{g,\nu} & \longrightarrow & N_{g,\nu} & \longrightarrow & \mathbf{\Gamma}_{g,\nu} & \longrightarrow & 1 \\ & & & & & & \uparrow \wr & & \\ & & & & & & \mathbf{\Gamma}_{\mathbb{Q}} \simeq \mathbf{\Gamma}_{0,3} & & \end{array}$$

as corresponding to the algebraic points of a modular variety (rather here, a multiplicity) $M_{g,\nu\mathbb{Q}}|M_{g,\nu,\mathbb{Q}}$, of which $N_{g,\nu}$ is the arithmetic fundamental group, and $\widehat{\mathcal{T}}_{g,\nu}$ the geometric fundamental group.

I would like to examine this situation more closely, later on. For the moment, it seems prudent not to make any|any hasty conjectures for [d1] a direct description (i.e. not via U_{03}) of "admissible" outer operations. We shall therefore work for the moment with|on this notion in the "constructive" form (via U_{03}). 487

[p. 248]

If we have an outer[i1] π of type $(g\nu)|(g,\nu)$ with an admissible outer operation of $\Gamma \subset \mathbf{\Gamma}$, we expect that there will be a canonical oriented prediscretification on π_x (not invariant|invariant under Γ, of course !|) – but such that the corresponding arithmetization is). We shall even[i2], for an admissible actual[i3] action of $\Gamma^\natural$ on π, (lifting the given outer action)[i4], define a canonical corresponding oriented[i5] discretification $\pi_0 \subset \pi$ (replaced by a conjugate, when we conjugate [d1] the lifting $\Gamma^\natural \to \mathcal{E}$ by a $g \in \pi$) – all these oriented discretifications (corresponding to the different "points" of $B_{\pi,\Gamma^\natural}$) define one and the same oriented pre-[i6]discretification – and even one and the same strict oriented prediscretification.

The actual action of $\Gamma^\natural$ on π can be obtained (up to isomorphism) as follows:[i7] we take|shall take an open[i8] subgroup $\mathcal{E}' \subset \mathcal{E}_{03}$, whence extension

$$1 \to \pi' \to \mathcal{E}' \to \Gamma' \to 1$$

with $\pi' \subset \hat{\pi}_{03}$, hence $\pi' = \hat{\pi}'_0$ ($\pi'_0 = \pi' \cap \pi|\Pi_{03}$). We have an operation of Γ' on $I(\pi') = I(\pi'_0)$, we take it trivial (at the cost of passing to an open subgroup of Γ'), we choose $i \in I' \subset I(\pi')$, we plug the holes at I', [d2] whence π, an [d3i9] oriented[i10] discretification π_0, and an outer action of Γ' on it, which is lifted to an actual action thanks to i. We do indeed find in this way a 488

"lattice" – an oriented discretification[i1] in π – I say that it does not depend on the choices that have been made – in particular, that the automorphisms|automorphisms of $(\pi, a, \Gamma^\natural)$ carry π_0 into itself. Moreover, if we have two points x, y[i2] of $B_{\pi,\Gamma^\natural}$, whence $\pi(x)$, $\pi(y)$, among the classes of paths from x to y (which make|form a bitorsor under $\pi(y), \pi(x)$) there are some for which [d1] $\pi(x) \to \pi(y)$ sends $\pi_0(x)$ into $\pi_0(y)$, – when we restrict ourselves to these, we find a subgroupoid of the fundamental groupoid $\Pi_{1|\cdot}(\pi, \Gamma^\natural)$, which this time is a connected loop groupoid. We shall take note that Γ does[i3] not operate on this groupoid, although it operates on the set of its objects. 489

[p. 249]

35 The injectivity of $\Gamma_{\mathbb{Q}} \longrightarrow \mathrm{Autext}_{\mathrm{lac}}(\widehat{\Pi}_{0,3})$.

proved modulo lemma 2 below —

Theorem 1 Let $\Gamma = \mathrm{Gal}(\overline{\mathbb{Q}}_0/\mathbb{Q})$, where $\overline{\mathbb{Q}}_0$ is the algebraic closure of $\mathbb{Q}$ in $\mathbb{C}$, let us consider the canonical homomorphism

$$(1) \qquad \Gamma \xrightarrow{\Theta} \widehat{\mathcal{T}}_{0,3} = \mathrm{Autext}_{\mathrm{lac}}(\widehat{\Pi}_{0,3}).$$

This homomorphism is injective.

Proof.

Lemma 1 Let $x \in \mathbb{Q}$, $x \neq 0, 1$ i.e. $x \in U_{0,3}(\mathbb{Q})$, let us choose a [d1] path on $\mathbb{P}^1(\mathbb{C})$ from $P = -\overline{j}|\overline{J}$ (base point for defining $\Pi_{03} = \pi_1(U_{0,3}(\mathbb{C}), P)$ — N.B. $U_{03} = \mathbb{P}^1_{\mathbb{Q}} \setminus \{0, 1, \infty\}$) hence an isomorphism $\pi_1(U_{0,3\overline{\mathbb{Q}}_0}, x) \simeq \widehat{\Pi}_{0,3}$, and by transport of structure an actual[i1] action of Γ on $\widehat{\Pi}_{0,3}$ (not just outer). Then K=Ker Θ operates trivially on $\widehat{\Pi}_{0,3}$.

Proof. It suffices to see that the outer operation of K on $\pi_1(\overline{V})$, where $V = U_{0,3} \setminus \{x\}$, is trivial.[i2] By the result of Белый, there exists a morphism (defined over $\mathbb{Q}$, this is essential)

$$\mathbb{P}^1_{\mathbb{Q}} \longrightarrow \mathbb{P}^1_{\mathbb{Q}},$$

[d2]étale over $U_{0,3} = \mathbb{P}^1_{\mathbb{Q}} \setminus \{0, 1, \infty\}$, and such that $x \longmapsto 0$. Let U' be the induced étale covering of $U_{03} = U$, [d3] $\pi' = \pi_1(\overline{U'})$ its geo- 490

[p. 250]

Returning to $\pi_1(\overline{V})$, we thus see that the image of K in $\mathrm{Autext}\,\pi_1(\overline{V})$ is finite, hence the image of K in $\mathrm{Aut}\,\widehat{\Pi}_{03}$ is finite. It moreover consists of inner automorphisms, so Lemma 1 will be a consequence of

Lemma 2 Every inner automorphism of finite order of $\widehat{\Pi}_{0,3}$ (free profinite group on two generators) is trivial. More precisely: $\widehat{\Pi}_{0,3}$ has a center reduced to $\{1\}$, and every element of $\widehat{\Pi}_{0,3}$ of finite order is reduced to 1.

This is a statement of pure profinite algebra, which I put off until later, to be done with the "geometric" part of the proof of the theorem.

Lemma 3 For every|every nonempty[i1] open $V \subset \mathbb{P}^1_{\mathbb{Q}}$, considering[i3] the outer action of Γ on $\pi_1(\overline{V})$, its restriction to K is trivial.

[scan 495]

[p. 251]

$$\pi' = \pi_1(\overline{V}, y) \hookrightarrow \pi\ (\simeq \widehat{\Pi}_{0,3}) = \pi_1(\overline{U}, x),$$

compatible with an actual action of Γ on these groups. By lemma 1 [d1]the[i1] induced action of K on $\pi = \pi_1(\overline{U}, x)$ is trivial, hence also its action on the subgroup π'. A fortiori the outer action is trivial, q.e.d.

We can now prove

Lemma 4 $K = (1)$ (i.e. the theorem!)

Indeed, under the conditions of lemma 2,[i2] the action of [d2]K[i3] on the set $I = S(\overline{\mathbb{Q}}_0)$, where $S = \mathbb{P}^1_{\mathbb{Q}} \setminus V$, is deduced from the outer action of [d3]K[i4] on $\pi_1(\overline{V})$, if card $I \geq 2$,[i5] as the action on the conjugacy classes of "loop subgroups|subgroups". As K operates trivially on the outer group, it operates trivially on I. This being true for every V, we see that the action of K on $\mathbb{P}^1(\overline{\mathbb{Q}}_0) = \overline{\mathbb{Q}}_0 \cup \{\infty\}$[i6] is trivial, i.e. its action on $\overline{\mathbb{Q}}_0$ is trivial, hence $K = (1)$, q.e.d. Whew!

[scan 496]

It remains to set down the proof of lemma 2, which I am going to reformulate in a more general form:

Theorem 2 Let π be a free profinite group on a set finite I[i1] of cardinality ≥ 2.

Then:

a) The center of π is [d1] equal to (1).

b) There is not in π[i2] any element of finite order other than 1.

In the end I am stuck on a) – just as I do not see why the center of Γ (and of every open subgroup) must be reduced to (1). Consult Deligne about this!

For b), here is an expedient.

Let K be an algebraically closed field of characteristic 0, and let us consider the function field $L = K(x)$ of [d2] U[i3]$= \mathbb{P}^1_K \setminus$[d3] ($n+1$ points)[i4] [d4] ($n = \operatorname{card} I$). Then $\pi \simeq \pi_1(U)$, and it is a quotient of $\mathcal{E}_L = \operatorname{Gal}(\overline{L}/L)$. Since π is free, $\mathcal{E}_L \longrightarrow \pi$ lifts to $\pi \longrightarrow \mathcal{E}_L$, and it suffices to see 495

[p. 252]

that $\mathcal{E}_L$ has no element of finite order $\neq 1$.

But according to Artin, there is no automorphism τ^{i1} of finite order $\neq 1^{i2}$ of an algebraically closed field $\overline{L}$, except in the case where $\overline{L}$ is a quadratic extension of a [d1] maximal [d2]ordered[i3] field R^{i4}, [d3] which is the field of invariants of τ (hence τ of order 2 exactly).

[d4] But in this case|case we would have $R \supset L$, and $L^{i5} \supset K$, now in K the element -1 is a square, so R cannot be ordered; absurd!

Corollary 1 of Theorem 1 Let $X|U$ be an algebraic curve (smooth, geometric[ally] connected, quasi-projective) over k a finite extension of $\mathbb{Q}$, [d5] (I presume that the outer action of $\mathcal{E}_k^{\overline{k}}$ on $\pi_1(X|U_{\overline{k}})$ is faithful if U anabelian – failing to be able to prove it, I state:) Then there exists a nonempty open subset V of $X|U$ such that the outer[i6] action of $\mathcal{E}_k^{\overline{k}}$ on $\pi_1(V_{\overline{k}})$ is faithful. 496

[scan 498]

Proof. By Белый, we know that we can find $V \subset X$, which is an étale covering of $U = (U_{03})_k$, I say that this V will do. So let K be the kernel of the outer [d2]operation[i1] of $\Gamma = \mathcal{E}_k^{\bar{k}}$ on $\pi' = \pi_1(V_{\bar{k}})$. Let y be a closed point of V, rational over the finite extension k' of k, corresponding to an open subgroup $\Gamma' = \mathcal{E}_{k'}^{\bar{k}}$ of Γ, let $K' = \Gamma' \cap K$. Let x be the image of y in U, we have

$$\pi' = \pi_1(V_{\bar{k}}, y) \hookrightarrow \pi = \pi_1(U_{\bar{k}}, x),$$

and by construction the outer action of K' on π' is trivial, hence K' operates on π' by inner automorphisms. Now we have

m590

Marginal note. [m590] proved only modulo verification of (2), (4) below – for the corollary (2) is moreover sufficient...

Lemma 5 Let π be a profinite[i3] group with loops, π' an open subgroup, then every automorphism u of π which leaves π' stable and induces on π' an inner automorphism (resp. the identity) is inner (resp. the identity). 497

[p. 253]

Let us admit this lemma for the moment – it follows that the elements of K', which operate on π inducing inner automorphisms on π', induce|induce themselves inner automorphisms on π itself, i.e. that the outer action of K' on π is trivial. By theorem 1, we know on the other hand that the outer action of Γ' on π is faithful, hence $K' = (1)$. It follows that K is finite. But by Artin we know that the only finite subgroups $\neq (1)$[i1] of Γ are those generated by a "complex conjugation [d1]" τ, corresponding|corresponding to a|to the [d2]ordered|ordered[i2] maximal|maximal subfield between k and $\bar{k}$. But for such a τ we have $\chi(\tau) = -1$, hence the outer action of τ cannot be trivial – we win. In fact, the proof has shown this:

Corollary 2 Let $k|K$ be a [d3]field of characteristic 0[i3], 498

[scan 500]

[d1]U a curve[i1] algebraic (smooth etc.) over k, such|such that $\mathcal{E}_k^{\bar{k}} = \Gamma$ operates faithfully on $\pi_1(U_{\bar{k}})$ (outer operation).

Then for every geometric[ally] connected étale covering V of U, the outer operation of [d2] Γ on $\pi_1(V_{\bar{k}})$ is also faithful.

Remains to prove lemma 5. It suffices to prove it in the resp. case – the other follows from it at once. [d3]If π has at least one class of loops (case of a curve[i2] [d4]algebraic affine i.e. nonproper), then π is[i3] [d5] free – and lemma 5 [d6]is valid[i4] precisely for such groups. If $(\ell_i|h_i)_{1\leq i\leq \nu}$ is a system of generators, let L_i be the closed subgroup generated by $\ell_i|h_i$, we shall admit that $\forall n \in \mathbb{N}^*$ not proved!

$$(2) \qquad L_i = \mathrm{Centr}_\pi(L_i^n|\ell_i^n)$$

This granted, if the automorphism u of π induces the identity on π', $\exists n \in \mathbb{N}^*$ such that $\forall 1 \leq i \leq \nu$ $u(\ell_i|h_i{}^n) = \ell_i|h_i{}^n{}_r$, hence $u(\ell_i|h_i)$ centralizes $\ell_i|h_i{}^n = u(\ell_i|h_i)^n$, 499

and we finish as above.

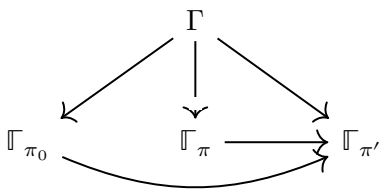
Remark The strongest faithfulness result in the direction of the present §, concerning actions of $\mathbb{\Gamma}$ and of its open subgroups, would be the following: if V is an anabelian algebraic curve over the finite extension k of $\mathbb{Q}$, with the algebraic closure $\bar{k}$, then not only should the outer action of $\mathcal{E}_k^{\bar{k}} = \Gamma$ on $\pi_1(V_{\bar{k}})$ be faithful, i.e.

$$\Gamma \longrightarrow \widehat{\widehat{\mathcal{T}}}(\pi)$$

m595

Marginal note. m595 this homomorphism[m] is automatically factored through the subgroup $\mathcal{N}(\pi)$ which interests us [illeg. 1]|normalizes $\widehat{\mathcal{T}}(\pi)$

injective, but even the composite homomorphism



$$\Gamma \longrightarrow \mathcal{N}_4(\pi)|\mathcal{N}_\Delta(\pi) \longrightarrow \mathcal{N}(\pi)/\widehat{\mathcal{T}}^+(\pi) \simeq \mathbb{\Gamma}_\pi$$

should be injective (in which case it will even be an isomorphism, since it is surjective by the very construction of $\mathcal{N}(\pi), \mathbb{\Gamma}_\pi$...) Some heuris-

[scan 503]

[p. 255]

tic arguments made previously (probably less convincing than those of the present § !) seem to indicate that this would be the case at least when V is an étale covering of $U = (U_{03})_k$, in which case indeed the homomorphism $\Gamma \longrightarrow \mathbb{\Gamma}_\pi$ fits into a commutative diagram

where $\pi_0 = \pi(U_{\bar{k}})$, so that π is an open subgroup of π_0, and $\pi''|\pi'$ is a suitable open subgroup, characteristic in π_0. If we could show that $\Gamma_{\pi_0} \longrightarrow \Gamma_{\pi'}$ is injective (which is $\pm$ a matter of profinite algebra), this would likewise be true of the composite $\Gamma \hookrightarrow | \subset \Gamma_{\pi_0} \longrightarrow \Gamma_{\pi'}$, thus also of $\Gamma \longrightarrow \Gamma_{\pi}$. Thus modulo this hypothesis on profinite groups, and using Belyi, we find that

For this, consider the quotient scheme

$$Y = \underbrace{\mathbb{P}^1_{\mathbb{Q}}}_{X} / \mathfrak{S}_3$$

with the three points a_0, a_1, a_∞ [i1] of Y, rational over $\mathbb{Q}$, a_0 [i2] corresponding to the orbit [d1] $\{0, 1, \infty\}$, a_1 to the orbit $\{-1, \frac{1}{2}, 2\}$, and a_∞ to the orbit $\{-j, -\bar{j}\}$ of $\mathfrak{S}_3$ (which exhausts the set of geometric "singular" orbits). We know that Y is a projective line (over $\overline{\mathbb{Q}}$ a priori), which we pin by a_0, a_1, a_∞ as points $0, 1, \infty$, (thus $Y \simeq \mathbb{P}^1_{\mathbb{Q}}$ – the [d2] morphism $X \longrightarrow Y$ is thus identified with a well-determined morphism

$j = \exp \frac{2i\pi}{3}$

$$(3) \qquad f : \begin{array}{ccc} \mathbb{P}^1_{\mathbb{Q}} & \longrightarrow & \mathbb{P}^1_{\mathbb{Q}} \\ \| & & \| \\ X & & Y \end{array}$$

[d3] which makes X a Galois covering|covering of Y, with group $\mathfrak{S}_3$, étale over|over $\mathbb{P}^1_{\mathbb{Q}} \setminus \{0, 1, \infty\}$, with ramification indices at these points $2, 2, 3$. From the point of view of the geometry of maps (placing oneself|immersing oneself over the base field $\mathbb{C}$), we consider the

above extend to this setting, and thus provide a homomorphism [d1] of extensions[i1]

$$\begin{array}{ccccccccc} 1 & \longrightarrow & \widehat{\Pi}_{03} & \longrightarrow & \mathcal{E}_{03} & \longrightarrow & \Gamma & \longrightarrow & 1 \\ & & \downarrow & & \downarrow & & \| & & \\ 1 & \longrightarrow & \widehat{\Pi}'_{03} & \longrightarrow & \mathcal{E}'_{03} & \longrightarrow & \Gamma & \longrightarrow & 1 \end{array} \tag{9}$$

, modulo conjugation by an inner automorphism of Π'_{03}.
m601

Marginal note. [m601] (9 bis) $\widehat{\Pi}_{0,3} \longrightarrow \widehat{\Pi}'_{0,3}$ fits into an exact sequence

$$\boxed{1 \longrightarrow \widehat{\Pi}_{0,3} \longrightarrow \widehat{\Pi}'_{0,3} \longrightarrow \mathfrak{S}_3 \longrightarrow 1}$$

and ditto for the discrete groups

$$\boxed{1 \longrightarrow \Pi_{0,3} \longrightarrow \Pi'_{0,3} \longrightarrow \mathfrak{S}_3 \longrightarrow 1}.$$

That said, let K be the kernel of the outer operation of Γ on Π'_{03}. One then sees that [d2] the outer operation of K on the open subgroup $\widehat{\Pi}_{03}$ takes place through a finite group (in fact, through the intermediary of[i2] $\widehat{\Pi}'_{03}/\widehat{\Pi}_{03} \simeq \mathfrak{S}_3$ ...) – which implies, by theorem 1 of the § above, that the group K itself is finite. Thus by Artin one has $K = 1$ or $K = (1, \tau)$, τ complex conjugation. But since $\chi(\tau) = -1$ it is obvious that the outer operation of τ on Π'_{03} (nor even on $(\Pi'_{03})^*_{\mathrm{ab}}$ [d3])[i3] is not trivial... [d4] This proves the proposition.

[scan 516]

At the level of discrete groups, one does define

$$\Pi_{03} \longrightarrow \mathrm{Sl}(2,\mathbb{Z}) \tag{22}$$

$$\begin{cases} \ell_1 & \longmapsto & u_4 \\ \ell_\infty & \longmapsto & u_6 \\ \ell_0 & \longmapsto & (u_6 u_4)^{-1} = u_4^{-1} u_6^{-1} \end{cases}$$

and $\mathrm{Sl}(2,\mathbb{Z}) \simeq \mathcal{T}^{+}_{11}$ [i1] identifies with the quotient of $\Pi_{0,3}$ by the invariant subgroup generated by the elements

$$\ell_1^4,\ \ell_\infty^6,\ (\ell_1^2)(\ell_\infty^3)^{-1}\ .$$

Besides, Π_{03} can be interpreted as a Teichmüller group $\mathcal{T}^{!+}_{0,4}$, and (22) as a homomorphism [m603]

Marginal note. [m603] indeed, $\mathcal{T}^{!}_{g,\nu}$ is an extension of $\mathcal{T}^{!}_{g,\nu-1}$ by $\Pi_{g,\nu-1}$ (if $(g,\nu-1)$ anabelian) and ditto for the $\mathcal{T}^{+}$, $\mathcal{T}^{!+}_{0,3} = (1)$!

$$\mathcal{T}^{!+}_{0,4} \longrightarrow \mathcal{T}^{+}_{11} \tag{23}$$

which I suspect extends to a homomorphism

$$\begin{array}{ccc} \mathcal{T}^{!}_{0,4} & \longrightarrow & \mathcal{T}_{11} \\ \wr & & \\ \text{extension of } \{1,\tau\} \text{ by } \Pi_{0,3},\ \text{which is none other than the cartographic group triangulated weighted unoriented} & & \wr \\ & & \mathrm{Gl}(2,\mathbb{Z}) \end{array} \tag{24}$$

not yet defined

I interpret the first side of (23) [i2] as the Π_1 "transcendental geometric" of the|of the modular|modular topos

[p. 264]

$\mathbb{M}^!_{0,4}$, classifying [d1] projective lines[i1] with four distinct points numbered from 1 to 4; and the second side|right-hand side of (23) is the transcendental π_1 of the modular topos $M_{1,1}$, classifying elliptic curves (with a fixed origin). One should therefore be able to define, at the level of [d2] modular multiplicities over $\mathbb{Q}$

$$(25) \qquad (\mathbb{M}^!_{0,4})_{\mathbb{Q}} \longrightarrow (\mathbb{M}_{1,1})_{\mathbb{Q}}$$

which would give rise to (23). [d4]

But one sees at once that one has a canonical isomorphism

$$(26) \qquad \mathbb{M}^!_{0,4} \simeq U_{0,3}$$

(I drop the subscripts $\mathbb{Q}$), and giving (25) thus also amounts to giving a family of elliptic curves over $U_{0,3}$.

But if λ is the "variable" $\in U_{0,3}$", taking "the" quadratic covering E_λ of [d5] $\mathbb{P}^1$ ramified at $0, 1, \infty, \lambda$,

[scan 518]

one finds an elliptic curve, with four marked points [d1] above $0, 1, \infty, \lambda$ — of which one can take the point above 0 as origin — then the other points are the three points of order 2, indexed resp. by $1, \infty, \lambda$.

More precisely: over any base scheme S[i1], except that 2 should be invertible there (residual characteristics all $\neq 2$), [d2] one has a[i2] functor which goes [d3] from the category of systems (E, α, β) of a[i3] relative|relative elliptic|elliptic curves|curve (homogeneous|homogeneous) [d5] over S, and [d6] α, β [d8] two[i4] sections of E which form a basis of ${}_2E$ as a locally constant[i5] scheme in $\mathbb{F}_2$-Modules (a local system of $\mathbb{F}_2$-modules) on S [giving rise to: $\gamma = \alpha + \beta$, as a third rogue — so that (β, γ),|. [d9] etc[i6] are in fact also bases) — to the category of projective-line bundles P over S, with four sections $u_0, u_1, u_\infty, \lambda$[i7] marked distinct at every point, by associating to E the quotient $E/\pm 1$, equipped with the sections $u_0, u_1, u_\infty, \lambda$ which are the images resp. of $0, \alpha, \beta, \gamma = \alpha + \beta$
m605

Marginal note. [m605] it amounts to the same thing to say that one has|the three sections α, β, γ of ${}_2E$ over S, which are $\forall s \in S$, [d10] distinct and hence|everywhere $\neq 1$.

[p. 265]
m606

Marginal note. m606 The pages which follow are needlessly complicated, with the introduction of the $M|\mathbb{M}'_{1,1}$, $\mathcal{T}'_{1,1}$ etc. – it is enough to go at it brutally|simply with the elliptic curve $y^2 = \sqrt{x(x-1)(x-\lambda)}$, over $U_{0,3}$, to [illeg. 1] have $U_{0,3} \longrightarrow M|\mathbb{M}_{1,1}$ cf. below…

and this functor is almost an equivalence of categories. What it lacks in order to be one, is that for a relative elliptic curve E, the symmetry $x \mapsto -x$[i1] of E – which is a nontrivial automorphism – operates trivially on the corresponding object $E/\pm 1$. So one must take the|the [d1] stack[i2] over (Sch), obtained from that of elliptic curves by starting by taking $\mathrm{Isom}(E,F)' = \mathrm{Isom}(E,F)/\pm 1$, then one will take the stack associated to a prestack (the objects over S are the "relative elliptic curves up to symmetry over S"). This|This|The stack is representable by a modular multiplicity $M|\mathbb{M}'_{1,1}$, [d2] having as its geometric fundamental group $\mathrm{Sl}(2,\mathbb{Z})^\wedge/\pm 1$ precisely, obtained [d3] for example from the modular varieties with Jacobi rigidification of level n, $M|\mathbb{M}_{11}[n]$ – with group $\mathrm{Sl}(2,\mathbb{Z}/n\mathbb{Z})$ operating on it, so that

$$M|\mathbb{M}_{11} \simeq (M|\mathbb{M}_{1,1}[n], \mathrm{Sl}(2,\mathbb{Z}/n\mathbb{Z})) \tag{27}$$

moreover|one notes that the central subgroup $(\pm 1)|\{\pm 1\}$ of[i3] $\mathrm{Sl}(2,\mathbb{Z}/n\mathbb{Z})$ operates trivially on $M|\mathbb{M}_{11}[n]$, so one can let the quotient group $\mathrm{Sl}(2,\mathbb{Z}/n\mathbb{Z})' = \mathrm{Sl}(2,\mathbb{Z}/n\mathbb{Z})/\pm 1$ operate, and set

[scan 521]

[p. 266]

which identifies $\mathcal{E}_{0,3}$ with a subgroup open[illeg. 1][i1] of index 6 of $\mathcal{E}'_{1,1} = \mathcal{E}_{1,1}/(\pm 1)$, and ditto for $\widehat{\Pi}_{0,3}$ in $\widehat{\mathcal{T}}'^{+}_{1,1}$. We thus find an iso[d1]morphism

$$(32)\qquad \widehat{\Pi}_{0,3} \overset{\sim}{\to} \left(\operatorname{Ker}\begin{pmatrix} \widehat{\mathcal{T}}^{+}_{11} & \longrightarrow & \mathfrak{S}_3 \\ \wr & & \wr \\ \mathrm{Sl}(2,\mathbb{Z})^{\wedge} & & \mathrm{Sl}(2,\mathbb{F}_2)\end{pmatrix}\right)/\pm 1$$

$$\begin{array}{ccc} & & \operatorname{Ker}(\widehat{\mathcal{T}}'^{+}_{1,1} \longrightarrow \mathfrak{S}_3) \\ & & \wr \end{array}$$

compatible with the outer actions of Γ. We can also say that we have an extension structure

$$(33)\qquad \begin{array}{ccccccccc} 1 & \longrightarrow & \widehat{\Pi}_{0,3} & \longrightarrow & \widehat{\mathcal{T}}'^{+}_{1,1} & \longrightarrow & \mathfrak{S}_3 & \longrightarrow & 1 \\ & & & & \wr & & \wr & & \\ & & & & \mathrm{Sl}(2,\mathbb{Z})^{\wedge}/\pm 1 & \to & \mathrm{Sl}(2,\mathbb{Z}_{/2}) & & \end{array}$$

compatible with the actions of Γ (Γ operating trivially on $\mathfrak{S}_3$).

I finally realize that what we get here is far from 22 — this homomorphism (22) is not at all injective, on the other hand it is surjective — and its values are not in $\mathrm{Sl}(2,\mathbb{Z})/\pm 1$, but in $\mathrm{Sl}(2,\mathbb{Z})$ itself! So I shall have to return again to a way of giving

[scan 522]

a remarkable arithmetico-geometric meaning to (22), and its extension to the corresponding profinite groups. For the moment, I confine myself to exploiting (33) a little. First of all I note that the arguments made in the scheme-theoretic setting, work also in the transcendental, complex analytic case, and then yield

$$(34)\qquad \Pi_{0,3} \overset{\sim}{\to} \operatorname{Ker}\begin{pmatrix} \mathcal{T}'^{+}_{11} & \longrightarrow & \mathfrak{S}_3 \\ \| & & \| \\ \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z})/\pm 1 & & \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z})\end{pmatrix}$$

compatible with (32), or again an exact sequence

$$(35)\qquad \begin{array}{ccccccccc} 1 & \longrightarrow & \Pi_{0,3} & \longrightarrow & \mathcal{T}'^{+}_{11} & \longrightarrow & \mathfrak{S}_3 & \longrightarrow & 1 \\ & & & & \wr & & \wr & & \\ & & & & \mathrm{Sl}(2,\mathbb{Z})/\pm 1 & & \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z}) & & \end{array}$$

,)|.,

[d1] We would like to interpret (35) and (33) as corresponding to the analogous exact sequences linked to diagram (9), relating $\Pi_{0,3}$ and $\Pi'_{0,3}$ — identifying $\Pi'_{0,3}$ with $\mathcal{T}'^{+}_{11}$, $\widehat{\Pi}'_{0,3}$ with $\widehat{\mathcal{T}}'^{+}_{11}$. I shall return to this later.

Remark One may ask whether the homomorphism

$$\widehat{\Pi}_{0,3} \longrightarrow \mathrm{Sl}(2,\mathbb{Z})^{\wedge}/\pm 1 \simeq \widehat{\mathcal{T}}^{+}_{11}/(\pm 1)$$

lifts (in a more or less natural way)

Apparatus for this scan

140-2-s522-D001 *deletion. Manuscript:* which
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 523]

[p. 267] to a homomorphism

$$\widehat{\Pi}_{0,3} \longrightarrow \mathrm{Sl}(2,\mathbb{Z})^{\wedge} \simeq \widehat{\mathcal{T}}^{+}_{1,1}$$

and ditto for the discrete groups

$$\Pi_{0,3} \longrightarrow \mathrm{Sl}(2,\mathbb{Z}) \simeq \mathcal{T}^{+}_{11}.$$

m607

Marginal note. [m607] Yes, one can lift, and it is more or less trivial... cf. below...

Of course, since $\Pi_{0,3}$ and $\widehat{\Pi}_{03}$ are free (with two generators) one can always lift — [d2]in exactly[i1] four ways, incidentally. (which necessarily, in the profinite setting, respect the discrete lattices). But can one do this while respecting the operations of Γ? For this it would suffice to be able to lift $U_{0,3} \longrightarrow M'_{1,1}$ to $U_{0,3} \longrightarrow M'^{t|\ell}_{11}$ (N.B. M_{11} is a [d4] $\mathbb{Z}/2$-gerbe over M'_{11}) — and I suspect, [d5] m608

Marginal note. [m608] not quite cf. the next page for a more reasonable formulation...

according to the "anabelian" yoga that I am trying to develop, that the converse must be true — that every lifting of $\widehat{\Pi}_{03} \longrightarrow \widehat{\mathcal{T}}'^{+}_{11}$ commuting with the operations of Γ is defined by such a lifting $U_{0,3} \longrightarrow M_{1,1}$. Now the existence of such a lifting $U_{0,3} \longrightarrow M_{1,1}$[i2] would mean exactly[i3] the existence of a family of elliptic curves over $U_{0,3}$, with

[scan 524]

Jacobi rigidification of level 2, which corresponds to the tautological invariant λ. I doubt that there is one, as I doubt that the lifting in terms of profinite groups with operations can be made.

To tell the truth, since $\widehat{\mathcal{T}}^{+}_{11} =^{i1} \mathrm{Sl}(2,\mathbb{Z})^{\wedge}$ no longer has trivial center, it is no longer [d1] reasonable in fact[i2] to want to "express everything" by the outer operations of Γ on $\widehat{\mathcal{T}}^{+}_{11}$, we must rather return to the extension $\mathcal{E}_{11} = \mathcal{E}_{M_{1,1}}$ of Γ by $\widehat{\mathcal{T}}^{+}_{1,1}$, and the question is whether the homomorphism

$$\mathcal{E}_{0,3} \longrightarrow \mathcal{E}'_{1,1} = \mathcal{E}_{1,1}/\pm 1$$

lifts to

$$\mathcal{E}_{0,3} \overset{?}{\to} \mathcal{E}_{11},$$

[d2]which is more[i3] stringent than finding a lifting $\widehat{\Pi}_{0,3} \longrightarrow \mathcal{T}^{+}_{11}$ compatible with the outer operations of Γ. To appreciate this difference, I note that Γ operates on the set E[i4] of the four liftings of $\widehat{\Pi}_{0,3} \longrightarrow \widehat{\mathcal{T}}^{+}_{1,1}$, (interpreted as outer homomorphisms), and the

[scan 525]

[p. 268] question posed in the weak form is whether there exists an element of E invariant under Γ. If there were none, there would in any case be an open subgroup of Γ, of index [d1]2

or 4[i1] [d2] [d3] which[i2] would leave an element invariant — so at the cost of passing to the [d4] corresponding finite extension of $\mathbb{Q}$, we find the lifting — and at the cost of passing to a slightly larger extension, the four possible liftings commute with the outer action of Γ. On the other hand, nothing proves that one can find a "germ of[i3] liftings" [d5] of $\mathcal{E}_{0,3} \longrightarrow \mathcal{E}'_{1,1}$ to $\mathcal{E}^G_{0,3} \longrightarrow \mathcal{E}^G_{1,1}$ (germs taken with respect to the subgroups open|open[i4] of $\mathcal{E}_{0,3}$ [d6] containing $\widehat{\Pi}_{0,3}$, or even of all the open subgroups) The obstruction to [d7]lifting over[i5] $\mathcal{E}_{0,3}$ [d8]itself[i6], i.e. to splitting a certain extension of $\mathcal{E}_{0,3}$ by [d9] ± 1), is

$$\alpha \in H^2(\mathcal{E}_{0,3}, \mathbb{Z}_{/2}) \tag{36}$$

— and nothing says that this cohomology class can be killed, by passing to an open subgroup of $\mathcal{E}_{0,3}$.

But in geometric terms, [d1] the relative elliptic curves sought over $U_{0,2}|U_{0,3}$ form $\dagger^{d2}|$the sections of a stack over $(U_{0,3})_{\mathrm{et}}$, which is a $^{d3}\mathbb{Z}_{/2}{}^{i1}$-gerbe — the obstruction therefore lies in a Brauer group

$$\beta \in H^2(U_{0,3}, \mathbb{Z}_{/2}), \tag{37}$$

now since $U = U_{0,3}$ is an algebraic [d4] affine curve over a field (it would suffice that it not be of type $0, 0$) it follows that the canonical homomorphism (with arbitrary torsion coefficients)

$$H^*(\mathcal{E}_U, -) \longrightarrow H^*(U, -)$$

is an isomorphism. Besides, it must be $\pm$ trivial that β is the image of α — which confirms the intuition|intention that [d5] if the lifting is possible at the level of profinite fundamental groups (arithmetico-geometric|arithmetico-geometric) it is also possible at the level of the modular multiplicities themselves, so that we have an existence of a relative elliptic curve over $U_{0,3}$ which…

[p. 269]

It is true that it is well known that a cohomology class (37) with torsion coefficients is killed, on passing to a finite extension of the [d1] base field ($\mathbb{Q}$ in this case). In fact, we have a spectral sequence

$$(38) \qquad H^*(U_{0,3}, \mathbb{Z}_{/2}) \Longleftarrow E_2^{pq} = H^p(\mathbb{Q}, H^q(\overline{U}_{0,3}, \mathbb{Z}_{/2})|))$$

and here $H^q(\overline{U}_{0,3}) = 0$ for $q \geq 2$, so we find an exact sequence

$$\cdots \quad \underset{\|}{E_2^{0,1}} \longrightarrow \underset{\|}{E_2^{2,0}} \longrightarrow H^2(U_{0,3}) \longrightarrow \underset{\|}{E_2^{1,1}} \longrightarrow \underset{\|}{E_2^{3,0}} \quad \cdots$$
$$H^0(\mathbb{Q}, H^1(\overline{U}) \qquad H^2(\mathbb{Q}, \mathbb{Z}_{/2}) \qquad H^1(\mathbb{Q}, H^1(\overline{U})) \underset{\mathbb{F}_2^2}{\wr} \qquad H^3(\mathbb{Q}, \mathbb{Z}_{/2}|\mathbb{F}_2)$$

I realize at last that the existence of a [d5] lifting, – i.e. of the hypothetical elliptic curve over $U_{0,3}$ – is completely trivial, it suffices to define it|it by the equation

$$y = \sqrt{x|\dot{x}(x-1)(x-\lambda)}$$

i.e.

$$y^2 - x(x-1)(x-\lambda) = F(x, y; \lambda] = 0$$

which defines an affine plane curve,

[p. 270] its center ± 1. (But in fact, there are exactly four subgroups of Γ_2 which realize this decomposition. So as not to make anyone|anyone jealous, one could look at the intersection of the four, which is a subgroup Γ_2 of index a divisor of $2^4 = 16$ it is the intersection of the kernels of|of the four homomorphisms $\Gamma_2 \longrightarrow$ Centre$(\Gamma_2) = \{\pm 1\}$, [m609]

Marginal note. [m609] N.B. That must be the kernel of $\mathrm{Sl}(2,\mathbb{Z})^{\wedge|*} \longrightarrow \mathrm{Sl}(2,\mathbb{Z}/4\mathbb{Z})$

As a subgroup of $\Pi_{0,3}$, its index is a divisor of 8 – It wouldn't surprise me if it were just the commutator group of $\Pi_{0,3}$,) which is of index 4 – there is a whole situation there to elucidate… . [m611]

it is true and it is ≃|even trivial…

Marginal note. [m611] It is not clear [d2] is invariant as a subgroup of [d3] $\mathcal{T}^+_{1,1} \simeq \mathrm{Sl}(2,\mathbb{Z})$, i.e. stable under the outer action of $\mathfrak{S}_3$ on $\mathrm{Sl}(2,\mathbb{Z})$ – I presume so, since $\mathfrak{S}_3$ also operates by outer automorphisms on $\Pi_{0,3}$ a priori… $\mathcal{T}^+_{11}/\Pi_{0,3}$ would be an interesting central extension of $\mathfrak{S}_3$ by $\{\pm 1\}$…

Of course, one should also make the homomorphism (42) explicit (defined modulo inner automorphisms) by its values on the generators l_0, l_1, l_2 – I shall perhaps return to this later.

Theorem The natural outer action of Γ_Q on $\widehat{\mathcal{T}}^+_{1,1}$, and even on $\widehat{\mathcal{T}}^{+\prime}_{1,1} = \widehat{\mathcal{T}}_{1,1}/(\pm 1)$, is faithful.

We use the fact that we have an injective outer homomorphism

$$\widehat{\Pi}_{0,3} \hookrightarrow \widehat{\mathcal{T}}'^{+}_{1,1}$$

compatible with the action of Γ, proceeding as for the proposition at the beginning (where $\widehat{\Pi}'_{0,3}$ played the role of $\widehat{\mathcal{T}}'^{+}_{1,1}$).

Corollary The canonical homomorphisms (surjective)

$$\Gamma_Q \longrightarrow \Gamma_{1,\nu} \qquad (\nu \geq 1) \tag{43}$$

are injective, hence isomorphisms.

It suffices to prove this for $\Gamma_Q \longrightarrow \Gamma_{1,1}$ (since $\Gamma_{1,1}$ is a quotient of $\Gamma_{1,\nu}$, $\nu \geq 1$ …), now we have a homomorphism $\dagger^{d1}$ $\Gamma_{1,1} \longrightarrow$ Aut ext $\widehat{\mathcal{T}}^+_{1,1}$ and we can consider the composite

Scans 531–540

[scan 531]

[p. 271]

$$\Gamma_{\mathbb{Q}} \longrightarrow \Gamma_{1,1} \longrightarrow \operatorname{Aut}\operatorname{ext}\widehat{\mathcal{T}}^{+}_{1,1} \longrightarrow \operatorname{Aut}\operatorname{ext}\widehat{\mathcal{T}}^{+\prime}_{1,1},$$

by the preceding theorem this composite is injective, hence also $\Gamma_{\mathbb{Q}} \longrightarrow \Gamma_{1,1}$, q.e.d.

Remark We really have the impression, with the proposition at the beginning, and the preceding result christened "theorem", of having proved the same thing twice, and with the same proof at that! So it is time, after this detour, to make sure that this really is so, i.e. that the homomorphism $\widehat{\Pi}_{0,3} \longrightarrow \widehat{\mathcal{T}}^{+\prime}_{1,1}$ which we have just used does indeed identify with the homomorphism $\widehat{\Pi}_{0,3} \longrightarrow \widehat{\Pi}'_{0,3}$, by means of a suitable isomorphism (which remains to be described), commuting with the outer actions of Γ, which we had set out to construct (cf. (10) to (20)) — and we lost it along the way, in

[p. 272]

37 Theory of Moduli of elliptic curves via Legendre (rigidification of level 2).)

I realize that I have made some nevertheless quite simple things rather complicated, in the preceding §First a pang of conscience about surface topology:

Proposition Let|Let[d1] X be a paracompact topological* surface, G a discrete group operating properly on X, we assume that for every $x \in X$, the stabilizer G_x operates faithfully on a neighborhood of x (so that G operates faithfully — in fact the two must be equivalent) preserving the local orientation (hence G_x is a cyclic group), so that $Y = X/G$ is a paracompact topological surface. Consider the set

$$X^! = \{x \in X \mid G_x \neq (1)\}$$

— which is a discrete subset of X stable under G — and the image $Y^! \subset \mid \in Y$ of $X^!$ — a discrete subset of Y — and the "signature" on $(Y, Y^!)$, for which the coefficient d_y $(y \in Y^!)$ is the ramification index $\operatorname{ord} G_x$ at the $x \in X$ over y. For every G-covering X' of X, let us then consider $X'/G = Y'$ as a space over Y. Then:

m612

Marginal note. [m612] Variant $\mathcal{G}$ operates [d2] [d3]on[i1] X, with|its invariant subgroup G in $\mathcal{G}$ satisfying the conditions opposite. We then have, putting [d4] $Y = X/G$ with an operation of $\mathcal{G}/G = \mathcal{H}$ on it:

$$\underline{\text{Rev}}.(X, \mathcal{G}) \cong \mid \simeq \underline{\text{Rev}}((Y, \underline{d}), \mathcal{H}),$$

hence

$$\Pi_1(X, \mathcal{G}, x) \xrightarrow{\sim} \Pi_1((Y, \underline{d}, \mathcal{H}), y).$$

Application

$$\mathfrak{S}_{0,3} \simeq \mathcal{T}'_{1,1} (\simeq \text{Gl}|\text{Sl}(2, \mathbb{Z})/\pm 1)$$

extension of $\mathcal{T}_{0,3} = \mathfrak{S}_3 \times \mathbb{Z}/2$ by Π_{03}

a) Y' is [d1] a topological surface,[i1] a ramified covering of Y, subordinate to the signature $\underline{d} = \underline{d}(X/Y)$.

b) The functor $X' \longmapsto Y' = X'/G$ is an equivalence of categories

$$(1) \qquad \text{Rev}(X, G) \xrightarrow{\approx} \text{Rev}_{\underline{d}}(Y)$$

N.B. We can make explicit a quasi-inverse functor, by associating to every ramified covering Y' of Y compatible with $\underline{d}$, [d3] the[i2] "normalized" (X, G)-covering (in a topological sense easy to make explicit) of $X \times_Y Y'$. We have an analogous statement for regular locally noetherian schemes of dimension 1, where the quasi-inverse functor is obtained by normalizing $X \times_Y Y'$.

Corollary Let $x \in X - X^!$, y its image in Y. We assume Y connected (i.e. that G operates transitively on the set of connected components of X). Then we have a canonical isomorphism

$$(2) \qquad \Pi_1(X, G; a|x) \xrightarrow{\sim} \Pi_1((Y, \underline{d}), y)$$

[p. 273]

whence, for X connected, a canonical exact sequence

$$(3) \qquad 1 \longrightarrow \Pi_1(X, x) \longrightarrow \Pi_1((Y, \underline{d}), y) \longrightarrow G \longrightarrow 1$$

N.B. We have ? an analogous corollary in the scheme-theoretic context, X and Y being regular schemes of dimension 1. — or, as the case may be, smooth relative schemes of relative dimension 1 over an S, but in this case one would have to (if I need it) take a little care to specify the statement|the statements in a reasonable form.

Example Let us take $X = \mathbb{P}^1(\mathbb{C}) \setminus \{0, 1, \infty\} = U_{0,3}(\mathbb{C})$, $G = \mathfrak{S}_3$ operating in the usual way, thus (with the [d2] conventions[i2] of the preceding §), [d3] identifying[i3] $\mathbb{P}^1(\mathbb{C})/(G = \mathfrak{S}_3)$ with $\mathbb{P}^1_{\mathbb{C}}$, with

$$(4) \qquad \begin{array}{rcll} (0, 1, \infty) & \longmapsto & 0 & d_0 = 2 \\ (2, -1, \frac{1}{2}) & \longmapsto & 1 & d_1 = 2 \\ (j, j) & \longmapsto & \infty & d_\infty = 3 \end{array}$$

we find $Y = \mathbb{P}^1(\mathbb{C}) \setminus \{0\}$, and $\underline{d} = 2\{1\} + 3\{\infty\}$.

We thus find a canonical isomorphism

$$(5) \qquad \Pi^1((U_{0,3}(\mathbb{C}), \mathfrak{S}_3), x) \simeq \Pi_1((\mathbb{P}^1(\mathbb{C}) \setminus \{0\}, \underline{d}), y)$$

[scan 537]

[p. 274]

the homotopy exact sequence for $\mathfrak{S}_3$ operating on $U_{0,3}(\mathbb{C})$. And we find likewise, in the arithmetico-geometric setting, working on the scheme $U_{0,3} = U_{0,3\mathbb{Q}}$ and its quotient $U_{0,3}/\mathfrak{S}_3 \simeq \mathbb{P}^1_{\mathbb{Q}} \setminus \{0\}$, with the signature $2\{1\} + 3\{\infty\}$ on it, the diagram of exact sequences

[(8) to the left of the second horizontal sequence. To the left and a little below $\widehat{\Pi}_{0,3}$: $\widehat{\mathcal{T}}^{+}_{0,4}$, followed by two short parallel oblique strokes (an = sign equating it with $\widehat{\Pi}_{0,3}$). To the left and a little below $\mathcal{E}_{0,3}$: $N^{!}_{0,4}$ (a short horizontal stroke against the $^{!}$), followed by two short parallel oblique strokes (an = sign toward $\mathcal{E}_{0,3}$). To the left and a little below the first $\Gamma_{\mathbb{Q}}$: $\Gamma_{0,4}$, followed by two short parallel oblique strokes (an = sign toward $\Gamma_{\mathbb{Q}}$).]

We now want to relate $U_{0,3}$, with the action of $\mathfrak{S}_3$ on it, to the modular multiplicity M_{11} for elliptic curves (subscripts $\mathbb{Q}$ understood). It is a pity, by the way, to work only over $\mathbb{Q}$ — I am going to work instead, over $\mathbb{Z}[1/2]$ — i.e. in residue|always characteristic $\neq 2$.

[scan 538]

In the preceding § I identified, somewhat murkily, $U_{0,3} = M^{!}_{0,4}$, with $M_{1,1}[2]'$, ([d1]over which[i1] $M_{1,1}[2]$ [d2]is a gerbe banded[i2] by $\mathbb{Z}/2$). The technical troubles (rather, the conceptual complications) are due to the fact that for elliptic curves (more generally, for abelian varieties of arbitrary dimension), if n is an integer ≥ 3, the "Jacobi rigidification of level n" really is a rigidification (i.e. every automorphism of a relative elliptic curve E which induces the identity on ${}_nE$ — kernel subscheme of $n.\mathrm{id}_E$ — is the identity — but it is no longer the same for $n = 2$, where $u|n$ is the identityid$_E$[i3] up above an open and closed subset of S, and $-\mathrm{id}_E$ on the complement. This suggests, for a better understanding, covering $M_{1,1}[2]$ by an $M_{1,1}(n)$, where n is a multiple of 2 — then $M_{1,1}(n)$ becomes an ordinary scheme of finite type over $\operatorname{Spec}\mathbb{Z}$ (its image in $\operatorname{Spec}\mathbb{Z}$ will be|will be the open set[i4] $\operatorname{Spec}\mathbb{Z}[1/n]$) and over $\operatorname{Spec}[1/n]$, the [d3]modular topos[i5]

[scan 540]

One must be careful that as a scheme over $\mathbb{Z}[1/n]$ (or over $\mathbb{Q}$, passing to the generic|generic fiber) $M_{1,1}[n]$ is not relatively connected (i.e. does not have geometrically connected fibers). In fact, an isomorphism

$$(\mathbb{Z}/n\mathbb{Z})^2_S \simeq {}_nE$$

implies, by passing to the $2^{\text{ième|ème}}$ exterior power, an isomorphism

$$(\mathbb{Z}/n\mathbb{Z})_S \xrightarrow{\sim} \Lambda^2_{\mathbb{Z}/n\mathbb{Z}}\, {}_nE \simeq \mu_n^{\otimes -1}(S)$$

whence an isomorphism

$$\mathbb{Z}/n\mathbb{Z} \simeq \mu_n(S)$$

which identifies (taking [d1] the image of 1 mod n) with a section of $\mu_n^*(S)$, where μ_n^* is the relative $(\mathbb{Z}/n\mathbb{Z})^*$-torsor over $\operatorname{Spec}\mathbb{Z}[1/n]$ of "primitive nth|n-th roots of 1". We thus have a canonical morphism

$$M_{1,1}[n] \longrightarrow \mu_n^* \tag{11}$$

and it is this morphism that has geometrically connected fibers in characteristic 0[i1]. Passing to the limit over variable n, we find over $\mathbb{Q}$

$$M_{1,1}[\infty] = \varprojlim_n M_{1,1}[n] \longrightarrow \mu_\infty^* \overset{\text{iso.can}}{\simeq} \operatorname{Spec}\Sigma \tag{12}$$

We have moreover (for the record)

$$\underline{\text{Theorem}} \qquad \widetilde{M}_{1,1} \simeq \mathbb{E}^1_{\mathbb{Z}} \qquad (\text{over } \operatorname{Spec}\mathbb{Z})$$

We can pin down such an isomorphism (defined|defines a priori modulo the integral affine group $X \longmapsto \pm X + n$, $n \in \mathbb{Z}$) by noting that there are in $\widetilde{M}_{1,1}$ two distinguished sections over $\mathbb{Z}$, whose values at the generic point correspond to the two isomorphism classes of elliptic curves in characteristic 0 (over $\mathbb{C}$, for example) which have automorphisms $\neq \mathrm{id}, -\mathrm{id}$ — the two groups of automorphisms that we obtain are moreover $\mathbb{Z}/4\mathbb{Z}$ and $\mathbb{Z}/6\mathbb{Z}$ (very easy for example by the transcendental|transcendental route). These are what are called unless I am mistaken the "anharmonic" elliptic curves. On an $M_{1,1}[n]$, the group of rational automorphisms $/k$ of an

elliptic curve described by a point x of $M_{1,1}[n](k)$ is canonically identified with the stabilizer of x in Γ_n:

$$\text{(15)} \qquad \mathrm{Aut}(E_x) \simeq (\Gamma_n)_x$$

[scan 543]

[p. 277]

— of course, we have suitable statements over an arbitrary base scheme, not necessarily a field. This already shows that the automorphisms of elliptic curves are linked in an essential way to the ramification of Γ_n operating on $M_{1,1}[n]|M_{1,n}[n]$. We thus find:

Proposition (Over Spec $\mathbb{Q}$) There are exactly two orbits of Γ_n operating on $M_{1,1}[n]$ which are "[d1]critical[i1]", and which correspond to stabilizers isomorphic resp. to $\mathbb{Z}/4\mathbb{Z}$ and $\mathbb{Z}/6\mathbb{Z}$, which are the groups of automorphisms of the corresponding ("anharmonic") elliptic curves. $n \neq 1, 2$

We will note|note that Γ_n does not operate faithfully|faithfully on $M_{1,1}[n]$ — the kernel of this operation is the central subgroup $\{\pm 1\}$, image of the corresponding group of $\mathrm{Gl}(2, \mathbb{Z})$ — it corresponds to the group of "universal" automorphisms $\pm \mathrm{id}_E$ of elliptic curves E. The quotient group

$$\text{(16)} \qquad \Gamma'_n = \Gamma_n / \{\pm 1\}$$

[d2] operates faithfully|faithfully, and we can look at the "mixed topos" $(M_{1,1}[n], \Gamma'_n)$ — we find

(21) factors as

$$(X, G) \longrightarrow \left(X, \underbrace{G/\mathfrak{z}|z}_{G'} \right) \xrightarrow{\sim} Y = X/G = X/G', \tag{22}$$

so that the morphism of multiplicities (21) is also identified, simply, with

$$\begin{array}{ccc} (M_{1,1}[2m], \Gamma_{2m,2}) & \longrightarrow & (M_{1,1}[2m], \Gamma'_{2m,2}) \\ & & \wr \\ & & M_{1,1}[2]' \end{array} \tag{23}$$

On the other hand, if we want to go down as far as $M_{1,1}[1]' = M'_{1,1}$, by passing to the quotient (in the "coarse" sense) of $M_{1,1}[n]$ by Γ'_n, the morphism

$$\begin{array}{ccc} (M_{1,1}[n], \Gamma'_n) & \longrightarrow & M_{1,1}[n]/\Gamma'_n \\ \| & & \| \\ M'_{1,1} & & \widetilde{M}_{1,1} \end{array} \tag{24}$$

is no longer an "isomorphism" i.e. is no longer an equivalence, for Γ'_n does not operate freely – it has (even in characteristic 0)[i1] ramification of degree $2, 3$.

[If however we exclude the anharmonic elliptic curves, its|it would work – it is "only in the neighborhood" of these elliptic curves that (24) is not an isomorphism…

[p. 280]

In fact, the arguments of the preceding § establish an isomorphism (valid over the[i1] $\operatorname{Spec}\mathbb{Z}[1/n]$ of $\mathbb{Z}[1/2]$)

$$M_{1,1}[2]' \simeq M^!_{0,4} \simeq U_{0,3} \tag{25}$$

(valid over $\operatorname{Spec}\mathbb{Z}[1/2]$)

m619

Marginal note. m619 N.B. the image of $M_{1,1}[2]'$ in $\operatorname{Spec}\mathbb{Z}$ is $\operatorname{Spec}\mathbb{Z}[1/n|2]$, while that of $M^!_{0,4} \simeq U_{0,3}$ is $\operatorname{Spec}\mathbb{Z}$ in all its entirety

and this isomorphism is compatible with the operations of [d1]

$$\Gamma'_2 \simeq \Gamma_2 = \mathrm{Gl}(2, \mathbb{Z}/2\mathbb{Z}) = \mathrm{Sl}(2, \mathbb{Z}/2\mathbb{Z}) \tag{26}$$

on $M_{1,1}[2]'$ on the one hand, of $\mathfrak{S}_3|\mathcal{S}_3$ on $U_{0,3}$ on the other hand|hands, when we consider the isomorphism

$$\begin{array}{ccc} \Gamma_2 & \xrightarrow{\sim} & \mathfrak{S}_3|\mathcal{S}_3 \\ \| & & \\ \mathrm{Gl}(2, \mathbb{F}_2) & & \end{array} \tag{27}$$

which associates, to every automorphism of $\mathbb{F}_2^2$, its action on the three nonzero elements, $\underline{\alpha} = (1,0)$, $\underline{\beta} =$[i2] $(0,1)$, and $\underline{\gamma} = (1,1) = \underline{\alpha} + \underline{\beta}$ (so that we have moreover) [d2]

$$\gamma = \alpha + |- \beta, \quad \alpha|\beta = \beta + |- \gamma, \quad \beta = \gamma + \alpha. \tag{28}$$

It would be necessary to make this compatibility explicit, by considering the natural action of $\mathfrak{S}_4|\mathcal{S}_4$ on $M^!_{0,4}$, $M^!_{0,n}$ being the modular multiplicity defined by

$$\underline{\mathrm{Hom}}_{\text{multiplicities}}(S, M^!_{0,n}) \simeq \begin{array}{c}\text{category of}\\ \text{relative curves|lines}\\ \text{over } S, \text{ locally isomorphic to } \mathbb{P}^1_S\\ \text{(for étale topology) and equipped}\\ \text{with } n \text{ sections mutually}\\ \text{disjoint numbered}\\ s_1|s_0, s_2, \dots s_n\end{array} \tag{29}$$

m620

Marginal note. m620 If we want representability for $n = 0, 1, 2$, it no longer suffices to work with the étale topology|the étale topologies — we need fppf topologies for example...

N.B. this really is representable by a multiplicity iff $n \geq 3$, i.e. if the stack in|of groupoids which we want to represent is "rigid" —i1 and then the multiplicity is even a scheme, isomorphic moreover canonical|canonically to the sub-i2scheme

$$\underline{\mathrm{Mon}}(I_{n-3}, U_{0,3}) \subset U_{0,3}^{I_{n-3}},$$

where here

$$I_{n-3} = \{i \in \mathbb{N} \quad 3 < i \leq n\}$$

— thus d3

$$M^!_{0,3} \xrightarrow{\sim} \operatorname{Spec} \mathbb{Z} \quad \text{(terminal scheme)}, \quad \text{and}$$

$$M^!_{0,4} \xrightarrow{\sim} U_{0,3} = \mathbb{P}^1_{\mathbb{Z}} \setminus \{\text{sections } \ 0, 1, \infty\} = \operatorname{Spec} \mathbb{Z}[T]\Big[\frac{1}{T(T-1)}$$

But we will keep in mind that there is a natural operation of $\mathfrak{S}_n|\mathcal{S}_n$ on $M^!_{0,n}$, hence on $\underline{\mathrm{Mon}}(I_{n-3}, U_{0,3})$ — d5 whereas we see a priori only the action of $\mathfrak{S}_3|\mathcal{S}_3 \times \mathfrak{S}_{n-3}|\mathcal{S}_{n-3}$ on the latter: the canonical isomorphism

$$M^!_{0,n} \simeq \mathrm{Mon}(I_{n-3}, U_{0,3}) \subset U_{0,3}^{I_{n-3}} \tag{30}$$

$$(\text{where } I_{n-3} = \{i \in \mathbb{N} \mid 3 < i \leq n\})$$

takes account only of the natural operations of the|of the

are canonically isomorphic to $\mathfrak{S}_{\tilde{I}}$ — hence to one another, [d1] by isomorphisms which [d2] are [d3] moreover [d4] deduced from the canonical bijections [d5]

$$(37) \qquad I \setminus \{i\} \xrightarrow{\sim} I \setminus \{j\} \qquad (i \neq j,\ i, j \in I)$$

canonical, equal to [d7] the transposition (not to the identity)[i2] on $I \setminus \{i, j\}$. This bijection is in fact the composite[i3] [d8]

$$I \setminus \{i\} \xrightarrow{\sim} \tilde{I} \xrightarrow{\sim} I \setminus \{j\} \qquad —$$

[d9] and for variable i, j, these isomorphisms form a transitive system of isomorphisms.

Returning to the action of $\mathfrak{S}_4$ on $M^!_{0,4}$, the key to understanding is given by this:

Proposition Consider the subgroup $V(I)$ of $\mathfrak{S}_I$ formed by 1 and the even involutions. Then the action of $V(I)$ on $M^!_{0,I}$ is trivial, &|If therefore [d14] $\mathfrak{S}_I$ acts on $M^!_{0,I}$ through $\mathfrak{S}_I/V(I) = \mathfrak{S}_{\tilde{I}}$.

m621

Marginal note. [m621] N.B. $M^!_{0,I}$ is defined in terms of I, for every set. I of cardinality. ≥ 3, as $M^!_{0,n}$

Corollary Let $i \in I$, then the action of $\mathfrak{S}_{I\setminus\{i\}} \subset \mathfrak{S}_I$ on $M^!_{0,I}$ is deduced from that of $\mathfrak{S}_{\tilde{I}}$ via the canonical isomorphism $\mathfrak{S}_{I\setminus\{i\}} \xrightarrow{\sim} \mathfrak{S}_{\tilde{I}}$

[p. 283]

Let us again work over $\mathbb{Q}$ (to fix ideas), and consider the fundamental groups of the modular multiplicities $M_{1,1}$, $M'_{1,1}$. We start from

$$\left\{\begin{array}{ccccc} M_{1,1} & \simeq & (M_{1,1}[n], \Gamma_n) & & (n \geq 3) \\ \downarrow & & \downarrow & & \\ M'_{1,1} & \simeq & (M_{1,1}[n], \underset{\Gamma_n/\pm 1}{\Gamma'_n}) & & \begin{array}{c}(n \geq 2),\ \text{replacing} \\ \text{for } n = 2 \quad M_{1,1}[2] \text{ by} \\ M_{1,1}[2]'\end{array} \end{array}\right. \tag{41}$$

which gives|give isomorphisms of outer groups

$$\begin{array}{ccccc} \pi_1(M_{1,1}) & \simeq & \pi_1(M_{1,1}[n], \Gamma_n) & & (n \geq 3) \\ \downarrow & & \downarrow & & \\ \pi_1(M'_{1,1}) & \simeq & \pi_1(M_{1,1}[n], \Gamma'_n) & & \begin{array}{c}(n \geq 2),\ \text{with} \\ \text{same grain of salt} \\ \text{for } n = 2)\end{array} \end{array} \tag{42}$$

since $M_{1,1}[n]$ is connected (even if it is not geometrically connected), we find [m622]

Marginal note. [m622] this is Kronecker's theorem on the irreducibility of the cyclotomic equation

$$\left\{\begin{array}{ccccccccc} 1 & — & \pi_1(M_{1,1}[n]) & \to & \pi_1(M_{1,1}) & — & \Gamma_n & \to & 1 \\ & & \downarrow{\scriptstyle\sim} & & \downarrow & & \downarrow & & \\ 1 & — & \pi_1(M_{1,1}[n]) & \to & \pi_1(M_{1,1}{}') & — & \Gamma'_n & — & 1 \end{array}\right. \tag{43}$$

which allows us to reconstruct|reconstruct $\pi_1(M_{1,1})$, as an extension of Γ_n, when we know|know $\pi_1(M'_{1,1})$ as an extension of Γ'_n, by inverse image via $\Gamma_n \to \Gamma'_n$. We find [d4]as[i1] is only right

Proposition $\pi_1(M_{1,1})$ is a central extension of $\pi_1(M'_{1,1})$ by $\{\pm 1\}$.
On the other hand, we have the exact sequences, [d5] of homotopy over $\operatorname{Spec}\mathbb{Q}$

[scan 559]

[p. 284]

For now I am going to exploit the second[i1] isomorphism (42), $n = 2$:

$$(48)\qquad \begin{aligned} \pi_1(M'_{1,1}) \simeq N'_{1,1} &\simeq \pi_1(M_{1,1}[2]', \Gamma_2 = \mathfrak{S}_3) \\ &\simeq \pi_1(U_{0,3}, \mathfrak{S}_3), \end{aligned}$$

where the last isomorphism corresponds to the isomorphism $\mathrm{int}(\sigma_1)$:[i3] $\mathfrak{S}_3 \simeq \mathfrak{S}_3$ made explicit in (40).

We do indeed find, as foreseen in the preceding § – and in an entirely conceptual way, the isomorphism d2 d3 of extensions
d4

$$
\begin{array}{ccccccccc}
1 & \to & \pi_1(\overline{M'_{1,1}}) = \widehat{\mathcal{T}}^{+\prime}_{1,1} \simeq \mathrm{Sl}(2,\mathbb{Z})^\wedge & \to & \pi_1(M'_{1,1}) \simeq N'_{1,1} & \to & \mathbb{\Gamma}_{\mathbb{Q}} & - & 1 \\
 & & \downarrow{\scriptstyle \sim} & & \downarrow{\scriptstyle \sim} & & \| & & \\
1 & \longrightarrow & \pi_1(\overline{U}_{0,3}; \mathfrak{S}_3) & \longrightarrow & \pi_1(U_{0,3}, \mathfrak{S}_3) & - & \mathbb{\Gamma}_{\mathbb{Q}} & - & 1 \\
 & & \simeq & & \simeq & & & & \\
 & & \widehat{\Pi}'_{0,3} & & \mathcal{E}'_{0,3} & & & &
\end{array}
\tag{49}
$$

Besides, taking up these reflections again in the transcendental context, we see that this isomorphism

$$
\begin{array}{ccc}
\widehat{\Pi}'_{0,3} & \xrightarrow{\quad\sim\quad} & \pi_1(\overline{M'_{1,1}}) \\
\| & & \simeq \\
\widehat{\Pi}_{0,3}/\{\ell_1^2, \ell_\infty^3\} & & \mathrm{Sl}(2,\mathbb{Z})'^\wedge = \mathrm{Sl}(2,\mathbb{Z})^\wedge/\pm 1
\end{array}
\tag{50}
$$

is associated with an isomorphism

$$
\boxed{
\begin{array}{ccc}
\Pi'_{0,3} & \xrightarrow{\sim} & \mathrm{Sl}(2,\mathbb{Z})' \simeq \mathrm{Sl}(2,\mathbb{Z})/\pm 1 \\
\| & & \\
\Pi_{0,3}/\{\ell_1^2, \ell_\infty^3\} & &
\end{array}
}
\tag{51}
$$

deduced from the isomorphism of complex analytic multiplicities

$$(52) \qquad M_{1,1}^{\mathrm{an}\,\prime} \simeq (U_{0,3}^{\mathrm{an}}, \mathfrak{S}_3)$$

We should all the same make the homomorphism (51) explicit – which is defined only modulo inner automorphisms, a priori, by explicit formulas – whereas its definition here comes out in a purely conceptual, "geometric" way (in the sense of relative algebraic geometry, of rational and elliptic curves over arbitrary analytic spaces). This is a key calculation, surely instructive,[i2] which should not present any particular difficulty…

I have somewhat dropped along the way[i3] in all this the "coarse" modular scheme $\widetilde{M}_{1,1}$, after having asserted that it is $\simeq \mathbb{E}^1_{\mathbb{Z}}$, and that there are two marked sections, whose [d2] values in characteristic 0 correspond [d3] two[i4] isomorphism classes of anharmonic elliptic curves. In terms of the isomorphism

Scans 561–570

[scan 561]

[p. 285]

$$(53) \qquad \widetilde{M}_{1,1} \simeq M_{1,1}[2]'/\Gamma'_2 \simeq U_{0,3}/\mathfrak{S}_3$$

one|now (valid over $\operatorname{Spec}\mathbb{Z}[1/2]$)

one does indeed find, over $S =^{i1} \operatorname{Spec}\mathbb{Z}[1/2]$, that $\widetilde{M}_{1,1}$ is obtained from a relative scheme Y,[i2] which is [d1] locally (étale)[i3] isomorphic to $\mathbb{P}^1_S$, by removing a section s (whose existence already implies that Y is globally|globally isomorphic to $\mathbb{P}^1_S$ - hence $Y - s(S)$ isomorphic to $\mathbb{E}^1_S$. In this

approach one thus feels like denoting by ∞ (not by 0, as in the theory of maps!) this section, which corresponds to the "points at infinity" $(0, 1, \infty)$ of $U_{0,3}$, or again to the "point at infinity" of $\widetilde{M}_{1,1}$. It is moreover easy to check a priori that (by the Deligne-Mumford compactification of $M_{1,1}$ and of $\widetilde{M}_{1,1}$) that $\widetilde{M}_{1,1}$ over the whole of $\operatorname{Spec}\mathbb{Z}$ is of the form $Y - \operatorname{Im} s$, where Y is smooth proper over $\operatorname{Spec}\mathbb{Z}$, and s a section - hence what one knows for example about the generic fiber, and the fact that $\mathbb{Z}$ is principal, imply that $Y \simeq \mathbb{P}^1_{\mathbb{Z}}$, and

[scan 562]

that one therefore has $\widetilde{M}_{1,1} \simeq \mathbb{E}^1_{\mathbb{Z}}$. To [d1] choose this isomorphism, one uses the two sections of $\mathbb{E}^1_{\mathbb{Z}}$, corresponding to the anharmonic curves. These two sections are not disjoint, they meet in characteristic 2 and characteristic 3. (As for what happens in characteristic $\neq 2$ i.e. over $\operatorname{Spec}\mathbb{Z}[1/2]$, one sees it clearly from the isomorphism 53 - [d2] for in characteristic 3 the two orbits

$$(2, -1, 1/2) \quad \text{and} \quad (j, \bar{j})$$

coincide and collapse into one and the same point). But taking one of these sections as zero section (unless I am mistaken it is the one corresponding to the elliptic curve richest in symmetries, namely|i.e. of|the group $\mathbb{Z}/6\mathbb{Z}$, that one takes - it is a matter of convention, of course - it is therefore also the orbit $\{j, \bar{j}\}$, corresponding to a stabilizer $\simeq \mathbb{Z}/3\mathbb{Z}$) - this determines the isomorphism $\widetilde{M}_{1,1} \simeq \mathbb{E}^1_{\mathbb{Z}}$ up to sign. The other section then becomes an integer of the form $\pm 2^a 3^b$ ($a, b \in \mathbb{N}^*$ - integers well determined whose value I|I have do not know by heart), and one finishes

[scan 563]

[p. 286]

normalizing by requiring that the sign be plus. Thus

Theorem (for the record - this is well known) There is a unique isomorphism

$$(54) \qquad \widetilde{M}_{1,1} \simeq \mathbb{E}^1_{\mathbb{Z}},$$

which [d1] in characteristic 0 gives to the anharmonic curve with automorphism group $\mathbb{Z}/6\mathbb{Z}$ the [d2]invariant[i1] 0, and to the one with group $\mathbb{Z}/4\mathbb{Z}$ an invariant [d3] > 0 (which will necessarily be $2^a 3^b$, with $a, b \in \mathbb{N}^*$ well determined, but forgotten by me…). $b = 3$, cf. below

In terms of the isomorphism

$$\widetilde{M}_{1,1} \simeq U_{0,3}/\mathfrak{S}_3 \subset \mathbb{P}^1/\mathfrak{S}_3$$

(valid over $\operatorname{Spec}\mathbb{Z}[1/2]$) this corresponds to [d5] an isomorphism between $\mathbb{P}^1/\mathfrak{S}_3$ and $\mathbb{P}^1$ which to the orbit $(0, 1, \infty)$ assigns ∞ (not 0) and to the orbit $(j, \bar{j})$ assigns 0 (not ∞), to the orbit $(2, -1, 1/2)$ the famous $2^a 3^b$ (and not 1). The function

modular invariant

$$(55) \qquad j(\lambda) \in \mathbb{Q}(\lambda)$$

which realizes this isomorphism, i.e. the|the [d6] morphism

is therefore related|related to the one inspired by the theory of maps, i.e. $f(\lambda)$, by

$$(57) \qquad j(\lambda) = 2^a 3^b f(\lambda)^{-1}.$$

Moreover $f(\lambda)$ (or $j(\lambda)$)[i1] is readily computed from knowledge of its zeros and its poles, with their multiplicities[i2], [d1] and the "normalization" by the value of f (or of j) on one of the sections $2, -1, 1/2$; one finds immediately:

$$(58) \qquad f(z) = \frac{3^3}{2^2} \frac{z^2(z-1)^2}{(z^2 - z + 1)^3}$$

hence

$$j(\lambda) = 2^{a+2}3^{b-3}\frac{(z^2-z+1)^3}{z^2(z-1)^2}. \tag{59}$$

Since $j(\lambda)$ must still make sense in characteristic 3 and not be constant, this shows moreover $b = 3$, so (59) can also be written

$$j(\lambda) = 2^{a+2}\frac{(z^2-z+1)^3}{z^2(z-1)^2}$$

- but one will recall|recalls that this formula is not relevant - does not allow one to compute [d3]the invariant of an[i3] elliptic curve - except in characteristic $\neq 2$, fortunately! To [d4]

[p. 287]

[d1]describe[i1]

$$M_{1,1} \longrightarrow \mathbb{E}^1_{\mathbb{Z}} \tag{60}$$

m626

Marginal note. [m626] and in particular to determine the other critical modular invariant 2^a3^3, i.e. determine a

also in a neighborhood of 2 - say in characteristic $\neq 3$ - one needs a study of elliptic curves which no longer goes by way of the representation (of Legendre, unless I am mistaken) $y^2 = \sqrt{x(x-1)(x-\lambda)}$, or again, by way of the Jacobi rigidification of level 2, but on the other hand by the one of level 3.

Remarks One sees at once that the quotient $\mathbb{P}^1_{\mathbb{Z}}/\mathfrak{S}_3$ identifies with $\mathbb{P}^1_{\mathbb{Z}}$, uniquely by taking as images of the orbits $(0, 1, \infty)$ and $(j, \bar{j})$ the sections 0 and ∞ (for example, following the convention corresponding to the theory of maps), and by taking as image of the orbit $(2, -1, 1/2)$ a [d2]rational[i2] which is > 0. This is possible a priori, for one notes that the [d3] orbits $(0, 1, \infty)$ and $(j, \bar{j})$ [d4] do not coincide in any characteristic, hence correspond to disjoint sections of $Y = \mathbb{P}^1_{\mathbb{Z}}/\mathfrak{S}_3$, whereas the remaining|constant orbit

[scan 566]

$(2, -1, 1/2)$ coincides with the first in characteristic 2, with the second in characteristic 3 (and these are the only coincidences that can occur). One therefore sees a priori that the third section will be of the form $2^\alpha/3^\beta$, with $\alpha, \beta \in \mathbb{N}^*$. The explicit calculation is moreover obvious, the composite morphism

$$(61) \qquad \mathbb{P}^1_{\mathbb{Z}} \xrightarrow{f_1^{*|\circ}} \mathbb{P}^1_{\mathbb{Z}}/\mathfrak{S}_3 \simeq \mathbb{P}^1_{\mathbb{Z}}$$

must be of the form $f_1^{*|\circ} = c.f^{*|\circ}$, with the constant $c \in \mathbb{Q}$[i1] chosen in such a way that $cf^{*|\circ}$[d1] reduces properly in all characteristics (which determines c modulo|modulo the sign) and that $f_1(-1) =$[i2d2] $cf^{*|\circ}(-1) = c$[i3] > 0 (which removes the indeterminacy of the sign). One then finds

$$(62) \qquad f_1(\lambda) = \frac{\lambda^2(\lambda-1)^2}{(\lambda^2-\lambda+1)^2} = \frac{2^2}{3^3} f(\lambda)$$

hence

$$(63) \qquad f_1(-1) = \frac{2^2}{3^3} \qquad (\text{so } \alpha = 2,\ \beta = 3).$$

But one will take note[d3] that in a neighborhood of characteristic 2,[i4] these calculations no longer concern $\widetilde{M}_{1,1}$ and $\widetilde{\widetilde{M}}|\widetilde{\widetilde{M}}_{1,1}$, where the configuration of the three sections[d4] is not the same as here…

Following the momentum of these reflections, it would be natural to look more closely at the scheme

$$(64) \qquad M_{1,1}[4], \quad \text{on which acts } \Gamma_4 = \mathrm{Gl}(2, \mathbb{Z}/4) \text{ via } \Gamma'_4 = \Gamma_4/\pm 1$$

and the homomorphism $\otimes$

$$(65) \qquad M_{1,1}[4] \longrightarrow M_{1,1}[2]' \simeq U_{0,3}$$

Compatible[i1] [d1]

$$\Gamma'_4 = \mathrm{Gl}(2, \mathbb{Z}/4)/\pm 1 \longrightarrow \Gamma'_2 = \Gamma_2 \simeq \mathrm{Gl}(2, \mathbb{Z}/2) \simeq \mathfrak{S}_3$$

m627

Marginal note. [m627]

[Above the arrow, a crossed-out inscription: [d2]. To the left of (65), a reference line connects the sign $\otimes$ to the marginal note.]

m628

Marginal note. [m628] in fact the kernel of the homomorphism $\mathrm{Gl}(k, A) \overset{[d3]}{\longrightarrow} \mathrm{Gl}(k, A/J)$ is always a commutative group $\circledast$ if J is a square-zero ideal of a ring A - so here $\mathrm{Ker}(\mathrm{Gl}(2, \mathbb{Z}/4\mathbb{Z}) \longrightarrow \mathrm{Gl}(2, \mathbb{Z}/2\mathbb{Z}))$ is a commutative group, and even a vector space over $\mathbb{F}_2$ - it is isomorphic to $\mathbb{F}_2^4$

$\circledast$ and even an A/J $(A/J)^4$

An immediate calculation, taking into account that

$$(\mathbb{Z}/4\mathbb{Z})^* \simeq \{\pm 1\}$$

, gives

$$\mathrm{card}\,\Gamma_4 = 2\underbrace{\mathrm{card}\,\mathrm{Sl}(2, \mathbb{Z}/4\mathbb{Z})}_{8\,\mathrm{card}\,\mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z})} = 16.\underbrace{\mathrm{card}\,\Gamma_2}_{6}$$

hence

$$(66) \qquad \mathrm{card}(\Gamma'_{4,2} = \mathrm{Ker}(\Gamma'_4 \longrightarrow \Gamma'_2)) = 8$$

i.e. $M_{1,1}[4]$ is a Galois covering of $M_{1,1}[2]'$, of [d4] order 8. Let us note that it is not geometrically connected over $\mathbb{Q}$, or over $\mathrm{Spec}\,\mathbb{Z}[1/2]$[i2], - since $M_{1,1}[4]$ lies over the quadratic extension μ_4^* [d5], of Spec $\underbrace{\mathbb{Z}[1/2]}_{\Lambda}$ say, which is none other than $\Lambda[i]$. One has [d6]a[i4i3] [d7] factorization of $M_{1,1}[4] \longrightarrow M_{1,1}[2]'$[i5] [d8]

[scan 568]

(67)

where now

$$M_{1,1}[4] \longrightarrow M_{1,1}[2]'_{S'} = (U_{0,3})_{S'}$$

is a Galois covering with group the kernel of $\Gamma'_{4,2} \xrightarrow{\det} \{\pm 1\}$, [d1]or again[i1] that of $\mathrm{Sl}(2,\mathbb{Z}/4\mathbb{Z})' \longrightarrow \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z})'$, which we shall denote by $S\Gamma'_{4,2}$, which is of order 4.

Proposition The group

$$(68) \qquad S\Gamma_{4,2} = \mathrm{Ker}(\mathrm{Sl}(2,\mathbb{Z}/4\mathbb{Z}) \longrightarrow \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z}))$$

is isomorphic to [d2] $\mathfrak{sl}(2,\mathbb{F}_2)$ (group of matrices of trace zero with coefficients in $\mathbb{F}_2$), with the obvious action|the obvious actions of $\mathrm{Sl}(2,\mathbb{F}_2)$ on it,[i2] and the subgroup ± 1 corresponds to scalar matrices - the quotient [d3]$S\Gamma'_{4,2}$ of the two[i3] isomorphic to [d4] $\mathbb{F}_2^2$ (in a silly way and not canonical at all!). [m630]

Marginal note. [m630] N.B. It is the 4 complements of this subspace $\mathbb{F}_2 \hookrightarrow | \subset \mathfrak{sl}(2,\mathbb{F}_2)$ [d5] which form a torsor under|over the dual of $V = \mathfrak{sl}/\mathbb{F}_2|\mathfrak{sl}(\mathbb{F}_2)$ which should correspond to the four [d6] liftings of $\pi_{0,3} \hookrightarrow T'^{+}_{1,1} = \mathrm{Sl}(2,\mathbb{Z})'$, i.e.|to $\pi_{0,3} \hookrightarrow \mathrm{Sl}(2,\mathbb{Z})$ cf. pages 259, 260 above on these questions

[d7] Viewing $M_{1,1}[4]$ as a Galois covering of $M_{1,1}[2]'_{S'} = (U_{0,3})_{S'}$, one finds geometrically "the" universal abelian covering of $U_{0,3}$ with group killed by 2 (and for good reason), which has as Galois group $(\mathbb{F}_2)^{\{0,1,\infty\}}$/Diagonale.

[scan 569]

[p. 289]

Finally, everything is essentially tautological - but an amusing calculation to do will be to "re[i1]describe the action of $\mathrm{Sl}(2,\mathbb{F}_2)$ on $\mathfrak{sl}(2,\mathbb{F}_2)$/scalar matrices" in such a way as to identify it with the action of $\mathfrak{S}_3$ on $\mathbb{F}_2^{\{0,1,\infty\}}$/diagonal.

As a covering of [d1]

$$(69) \qquad \widetilde{M}_{1,1\,S'} \simeq M_{1,1}[4]/S\Gamma'_4 \simeq M_{1,1}[2]'_{S'}/\Gamma'_2,$$

$M_{1,1}[4]$ is a Galois covering of order 24 (= 4.6), with group $\mathrm{Sl}(2,\mathbb{Z}/4\mathbb{Z})'$. [d2] It would be quite rare|welcome if one did not have an isomorphism

$$(70) \qquad \mathrm{Sl}(2,\mathbb{Z}/4\mathbb{Z})' \simeq \mathfrak{S}_4 \qquad \text{(automorphisms of the octahedron)}$$

and if $M_{1,1}[4]_{S'}$ were its covering [d3] [d4] of $\mathbb{P}^1_{S'} \setminus \{0,1,\infty\}$, with ramification compatible with $2\{1\}$ [d5] $+3\{\infty\}$, which corresponds to the octahedron & in the theory of maps - one should have over $S' = \mathrm{Spec}\,\mathbb{Z}[1/2][i]$ a canonical[i2] isomorphism [d6]

$$(71) \qquad M_{1,1}[4]_{S'} \simeq \text{Fermat curve} \quad x^2+y^2+z^2=0 \quad (\text{over } S')$$

m631

Marginal note. [m631] it would be better to write the Fermat equation here $x_0^2+x_1^2+x_\infty^2=0$

(whose automorphism group is precisely an extension of $\mathfrak{S}_3$ by $\mu_2^{\{0,1,\infty\}}$/diag!).

[scan 570]

To do things properly, one would have to make explicit the relation between elliptic curves E/S[i1] (over a scheme S over $\mathbb{Z}[1/2][i]$) equipped with a Jacobi rigidification of level 4 e_1, e_2 with $e_1 \wedge e_2 = [i]^{-1}$, and "nontrivial" solutions of the equation

$$(72) \qquad x^2+y^2+z^2=0$$

over S (i.e. the systems of sections $x, y, z \in \Gamma(S, \mathcal{O}_S^*)$ satisfying (72), modulo multiplication by a "scalar" $\alpha \in \Gamma(S, \mathcal{O}_S^*)$[i2] - or again, breaking the symmetry by putting $X = x/z$, $Y = y/z$, [d1] the solutions of the equation

$$X^2 + Y^2 = -1 \qquad (= i^2) \tag{73}$$

$(X, Y \in \Gamma(S, \mathcal{O}_S^*))$...

One has thus interpreted $M_{1,1}[2]'$, and (modulo some checks and a somewhat more thorough study) $M_{1,1}[4]$, in relation with [d2] regular weighted triangular[i3] maps - the "dihedral|dihedral" map of index 3|of order 3[i4] or universal weighted triangular map (three vertices $0, 1, \infty$,

[An almost circular outline, with a horizontal oval. Three filled dots are marked on the oval: 0 on the left, ∞ on the upper branch on the right, 1 on the lower branch on the right. The three portions of the oval join these three points.]

three edges, two faces which are triangles, type $(p, q) = (3, 3)$), and the octagonal map, which is a covering of order 4 of this one ([d3]étale[i5] away from the vertices $\{0, 1, \infty\}$),

There would be reason also to look at

Scans 571–575

[scan 571]

[p. 290]

more closely the congruential modular varieties $M_{1,1}[3]$ and $M_{1,1}[5]$, corresponding to "geometric" modular groups:

$$\left(\begin{cases} S\Gamma'_3 = \underbrace{\mathrm{Sl}(2,\mathbb{F}_3)}_{\substack{\text{order } 4.3.2 \\ =24}}/\pm 1 \quad \text{of order } 12 \;{}_{\dagger}\subset \underbrace{\mathrm{GP}(1,\mathbb{F}_3)}_{\text{order } 24} \simeq \mathfrak{S}_4 \\ \text{in fact, we must have } S\Gamma'_4 \simeq A_4 \\ \\ S\Gamma'_5 = \underbrace{\mathrm{Sl}(2,\mathbb{F}_5)}_{\substack{\text{order } 6.5.4 \\ =120}}/\pm 1 \quad \text{of order } 60 \subset \underbrace{\mathrm{GP}(1,\mathbb{F}_5)}_{\text{order } 120} \simeq \text{group of the biicosahedron} \end{cases} \right. \tag{74}$$

Unless I am mistaken, these groups are|†[d2] resp.[i2] the groups A_4 of the oriented tetrahedron, and the one A_5 of the oriented icosahedron. If I remember rightly, the cases $n = 2, 3, 4, 5$ exhaust the cases of congruential modular [d3]curves[i3] $M_{1,1}[n]$ which are rational – it is a remarkable thing that through them one finds all the regular finite[i4] polyhedra with triangles for faces [m632]

Marginal note. [m632] except one, with "folded-back edges" – the one in figure (76), cf. below…

– it was clear a priori|a-priori[i5], from the isomorphism|isomorphism between $\mathcal{T}'_{1,1}$ and the "triangula- oriented cartographic group" $\pi'_{0,3}$, that we should find again all the finite regular polyhedra with|†[d4] triangles for faces in this way, but not that this should be with congruence|congruences subgroups, very precisely. The table obtained is then the following

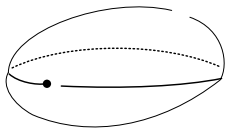
$$\begin{array}{lll} \text{group } G = S\Gamma'_n & \text{modular curve} & \text{type of regular oriented polyhedron} \\ \left\{ \begin{array}{l} D_3 \simeq \mathfrak{S}_3 \\ A_4 \\ \mathfrak{S}_4 \\ A_5 \end{array} \right. & \begin{array}{l} M_{1,1}[2]' \\ M_{1,1}[3] \\ M_{1,1}[4] \\ M_{1,1}[5] \end{array} & \begin{array}{l} \text{spherical bitriangle} \\ \text{tetrahedron} \\ \text{octahedron} \\ \text{icosahedron} \end{array} \end{array} \tag{75}$$

As other rational modular curves (not congruential) Galois over $\widetilde{M}_{1,1}$, there would still be the quotients of the preceding ones by invariant subgroups of the $S\Gamma'_n$, distinct from the whole group and from 1. One finds as possible quotients

a) Case $\mathfrak{S}_3$; the quotient ± 1 (via the sign)

b) Case A_4: the quotient $\mathbb{Z}/3\mathbb{Z} = C_3$ (via $\mathfrak{S}_4 \to \mathfrak{S}_3$, inducing $A_4 \to C_3$)

c) Case $\mathfrak{S}_4$: the quotient $\mathfrak{S}_3$, and the quotient $\{\pm 1\}$ of the latter.



(For d), there is nothing, A_5 being a simple group)

d1

The rational modular curves obtained are reduced to the two cases a) and b) (which are found again|found again in c)). In case a), one finds the quadratic[i1] covering of $Y = \mathbb{P}^1(\mathbb{C}) - \{0, 1, \infty\}$, which is unramified at ∞ (for the ramification index must divide 2 and 3), which therefore corresponds to the covering

$$y = \sqrt{x(x-1)}$$

and to the regular spherical map of type $(2, 1)$ (vertices of index 2, faces of index 1)

formed|formed of one vertex, on an edge (equator) bounding two faces which are monogons.

Case b) is the cyclic covering of order 3: ramified only at 0 and at ∞ (at 1 the ramification index must be a divisor of 2 and of 3, hence is 1) hence regular spherical map of

type $(3, 3)$, with edges which are loops [d1]folded back[i1]

(76)

: 1 single vertex, three folded-back edges coming out of it, one triangular face. [These modular varieties are too close to $\widetilde{M}_{1,1}$ – with an automorphism group (quotient of $\Gamma'_\infty = \mathrm{Sl}(2, Z|\mathbb{Z})$) too small, to be able to be rigidifying (the Galois-Poincaré group of the covering would have to be a multiple of 12(multiple of 4 and of 6 ?!)[i2], for [d2] the modular curve to have a chance of being rigidifying. These cases thus seem distinctly less interesting.

There would be reason moreover, in each of the three remaining cases of (75) (thus setting aside the first case, which corresponds to $M_{1,1}[2]'$ and is more or less understood), to make explicit the relation between the points of the corresponding rational curves, and between elliptic curves with[i3] Jacobi rigidifications, of level $3, 4, 5$ respectively. And there are surely precise things in Klein, but one would like to do things a little finer, which are valid simultaneously in all characteristics|every characteristic i.e. over general base schemes. This concern seems intimately linked to the question of the operations of $\Gamma_{\mathbb{Q}}$ on the isomorphism classes of maps, and

more particularly of regular spherical maps. It is quite extraordinary that Jean Malgoire, in the three years that the question has been there, has not yet touched it – God knows it is juicy!

Supplement on the cross-ratio.

Let x_1, x_2, x_3, x_4 be [d1]sections everywhere[i2] distinct[i1] of $\mathbb{P}^1_S$, we want to construct the corresponding section λ of $U|\mathbb{U}_{0,3} = \mathbb{P}^1_S - \{0,1,\infty\}_S$. Let a, b, c, d be sections (local) of $\mathcal{O}_S$, with [d2] $ad - bc$ invertible,[i3] such that

$$u = u_{a,b,c,d} : \quad z \longmapsto \frac{az+b}{cz+d} \tag{77}$$

transforms (x_1, x_2, x_3) into $(0, 1, \infty)$ – we shall therefore have

$$\lambda = u(x_4). \tag{78}$$

The conditions on $\xi|\dagger$[d3] (a, b, c, d) for $ux_1 = 0$ etc. are

$$\begin{cases} ax_1 + b = 0 \\ ax_2 + b = cx_2 + d \\ cx_3 + d = 0 \end{cases}$$

which give, if for example a is invertible (otherwise, we can assume c invertible…) on solving for b, c, d

$$\begin{cases} b = -ax_1 \\ cx_2 + d = a(x_2 - x_1) \\ cx_3 + d = 0 \end{cases} \qquad \begin{vmatrix} c = a\dfrac{x_2 - x_1}{x_2 - x_3} \\ d = -a\dfrac{x_2 - x_1}{x_2 - x_3}x_3 \end{vmatrix}$$

whence

$$\lambda = \frac{ax_4 + b}{cx_4 + d} = \frac{a(x_4 - x_1)}{a\frac{x_2 - x_1}{x_2 - x_3}x_4 - a\frac{x_2 - x_1}{x_2 - x_3}x_3} = \frac{(x_4 - x_1)(x_2 - x_3)}{(x_2 - x_1)(x_4 - x_3)}$$

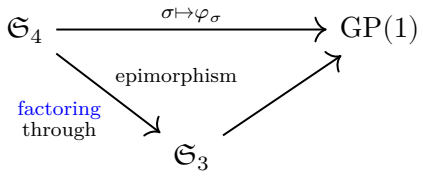
[scan 575]

[p. 292]

$$\lambda(x_1, x_2, x_3, x_4) = \frac{(x_4 - x_1)(x_2 - x_3)}{(x_2 - x_1)(x_4 - x_3)} \tag{79}$$



As a rational function in x_1, x_2, x_3, x_4, (with coefficients in a fixed integral domain) it is characterized by the two properties: a) invariance with respect to a (same) homographic transformation on the variables, x_1, x_2, x_3, x_4,[i1] [d1]

$$f(ux_1, ux_2, ux_3, ux_4) = f(x_1, x_2, x_3, x_4),$$

and[i2] b)

$$f(0, 1, \infty, x_4) = x_4$$

(with a grain of salt to give a meaning to the first side. We have moreover c) a remarkable symmetry property, which we [d2] make explicit by defining a homomorphism from $\mathfrak{S}_4$ into the homographic group (morally|normally, GP(1)) [d3]

in such a way that we have

$$\lambda(x_{\sigma^{-1}1}, x_{\sigma^{-1}2}, x_{\sigma^{-1}3}, x_{\sigma^{-1}4}) = \varphi_\sigma(\lambda(x_1, x_2, x_3, x_4)) \tag{80}$$

[p. 291bis]

38 Explicit determination of the homomorphism $\Pi'_{0,3} \xrightarrow{\sim} \mathfrak{S}^{+}_{0,3}$ (and of $\Pi'^{\sim}_{0,3}$ (unoriented triangulated cartographic group) $\xrightarrow{\sim} \mathfrak{S}_{0,3}$).

I feel like coming back to the proposition of the preceding § (page 262) with connected[i1] surface X, discrete group G operating properly, the stabilizers G_x[i2] of the $x \in X$ [d1] preserving the orientation and operating faithfully in a neighborhood of x … taking $Y = X/G$, equipped|equipped with the "signature" $\underline{d} = d(X/Y)$ defined by the ramification — whence an Isomorphism|isomorphism

$$(1) \qquad \Pi = \Pi_1((X,G),x) \xrightarrow{\sim} \Pi_1((Y,\underline{d}),y) = \Pi'$$

($x \in X$, y image of x in Y) which I would like to study more closely.

We have in $\Pi_1((Y,\underline{d}),y)$, for every $b \in \mathrm{Supp}\underline{d} = Y^!$, "truncated-loop subgroups", more precisely a conjugacy class of|of the subgroups quotients of $\mathbb{Z}/d_b\mathbb{Z}$, and more precisely still, a canonical outer homomorphism

$$(2) \qquad T_b|T_y \otimes_{\mathbb{Z}} \mathbb{Z}/d_b\mathbb{Z} \longrightarrow \Pi'$$

obtained by passage to the quotient from the outer homomorphism

$$(3) \qquad T_b|T_y \xrightarrow{k_y|k_b} \Pi_1(Y \setminus Y^!) \qquad (\longrightarrow \Pi_1((Y,\underline{d})))$$

(where T_b is the free $\mathbb{Z}$-module of rank 1 of "twisted integers" at b on Y). On the other hand, if $a \in X$ lies above b, the stabilizer G_a is [d2] a cyclic group of finite order $d_a = d_b$ — We have = an obvious canonical isomorphism

$$(4) \qquad G_a \simeq T_a \otimes_{\mathbb{Z}} \mathbb{Z}/d_a\mathbb{Z} \simeq T_b \otimes \mathbb{Z}/d_b\mathbb{Z}.$$

(N.B. $T_a \simeq T_b$ canonical[ly])

[scan 7]

On the other hand, to a is associated|associated a conjugacy class of splittings of the extension

$$(5) \qquad 1 \longrightarrow \Pi_1(X,x) \longrightarrow \Pi_1((X,G),x) \longrightarrow G \longrightarrow 1,$$

(cf. § 15)

$$(6) \qquad k_a : G_a \longrightarrow \Pi_1((X,G),x)$$

these classes of $\Pi_1(X,x|e)$-conjugacy[i1] of splittings (if $X \neq S^2$) correspond one-to-one to the fixed points of G_a operating on X. If we take the outer homomorphism defined|defined by (6) (thus conjugating|conjugating not only by the $\in \Pi_1(X)$, but by those of $\Pi_1(X,G)$ in its entirety) we find a 1-1 correspondence between the set[i2] of outer homomorphisms (6) which lift the inclusion

$$G_a \hookrightarrow G$$

(considered as an outer homomorphism), and the set of orbits of G in $X^!$, i.e. [d1] the points of $Y^!$. In summary

Proposition We have a bijection between $Y^!$ and the set of "maximal" outer homomorphisms $\varphi = \varphi_b : \Gamma \longrightarrow \Pi|\pi$[i3] of subgroups $\Gamma \subset G$, [d2] $\Gamma \neq 1$, into $\Pi_1(X,G)$ which lift the inclusion $\Gamma \subset G$[i4] (the said Γ are necessarily cyclic, the Γ 6

[scan 8]

[p. 292bis]

in question corresponding|corresponding to a $b \in Y^!$ being the stabilizers G_a in G of the [d1] $a \in X_b = X_b^!$. Moreover, the composite of the homomorphisms

$$(7) \qquad T_b \otimes \mathbb{Z}/n\mathbb{Z} \overset{(4)}{\simeq} G_a \xrightarrow{\varphi_a = \varphi_b} \Pi_1(X, G) \overset{(1)}{\sim\!\!\to} \Pi_1((Y, \underline{d}))$$

is none other (we might have guessed!) than "the "truncated loops" homomorphism (2).

Let us now suppose that X is of the form $\widehat{X} \setminus S$, $\widehat{X}$ a compact surface, S a finite subset of $\widehat{X}$ [d2]

$$(8) \qquad \begin{cases} X = \widehat{X} \setminus S \quad \text{thus} \quad Y = \hat{Y} \setminus T \quad \neq \emptyset \quad \text{with} \\ \hat{Y} = \widehat{X}/G \end{cases}$$

Let us consider, then, for every $a|b \in S$, the outer homomorphism

$$(9) \qquad k_a : T_a \longrightarrow \Pi_1(X) \hookrightarrow \Pi_1(X, G)$$

which I am going to compare with the composite

$$(10) \qquad T_b \xrightarrow{k_b} \Pi_1(Y) \longrightarrow \Pi_1(Y, \underline{d})$$

(for $b = \hat{f}(a)$), by means of the canonical isomorphism

$$(11) \qquad T_a \simeq T_b$$

If d_a again denotes the ramification index at a, we shall have a commutative compatibility diagram: 7

[scan 9]

(12)

We are going to apply this to the situation of $X = U^{\mathrm{an}}_{0,3}$, $G = \mathfrak{S}_3$, $\widehat{X} = \mathbb{P}^{1\mathrm{an}}$, $\hat{Y} \simeq \mathbb{P}^{1\mathrm{an}}$, with the map of passage to the quotient given|given by (page 286' (58))

$$(13) \qquad f(z) = \frac{3^3}{2^2} \frac{z^2(z-1)^2}{(z^2 - z + 1)^3}$$

$$f : \begin{cases} 0 \\ 1 \\ \infty \end{cases} \longrightarrow 0 \qquad \begin{cases} 2 \\ -1 \\ 1/2 \end{cases} \longrightarrow 1 \qquad \begin{cases} -\bar{j} \\ -j \end{cases} \longrightarrow \infty$$

Thus we see, with the notations of , that the generators l'_0, l'_1, l'_∞ of $\Pi'_{0,3}$ (satisfying

$$(14) \qquad l'_\infty l'_1 l'_0 = 1 \qquad {l'_1}^2 = {l'_\infty}^3 = \cdot 1 \qquad)$$

correspond, respectively, under the isomorphism

$$(15) \qquad \begin{array}{c} \mathfrak{S}^+_{0,3} = \Pi_1(U^{\mathrm{an}}_{0,3}, \mathfrak{S}_3) \\ \text{cartographic group} \\ \text{triangulated weighted oriented} \\ \underline{\text{mixed}} \end{array} \xrightarrow{\sim} \begin{array}{c} \Pi'_{0,3} = \mathcal{T}^{+\prime}_{1,1} \\ \text{cartographic group triangulated|triangul-} \\ \text{oriented} \qquad \simeq \mathrm{Sl}(2,\mathbb{Z})' \end{array}$$

to the elements denoted [d1]

$$(16) \qquad \left\{ \begin{array}{lll} \varepsilon_0, \varepsilon_1, \varepsilon_\infty & \longmapsto & l'_0 \\ (\text{such that } \varepsilon_i^2 = l_i) & & \\ \sigma_0, \sigma_1, \sigma_\infty & \longmapsto & l'_1 \\ \rho & \longmapsto & l'_\infty \end{array} \right| \quad \begin{array}{l} \text{mod} \\ \text{conjugacy} \end{array}$$

or ρ^{-1} ?

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 10]

[p. 293]
d1

This shows that we can find in $\Pi = \mathfrak{S}^+_{0,3}$ [i1] conjugates ε'_0 of ε_0, σ'_0 of σ_0, such that we have

$$(17) \qquad \rho\sigma'_0\varepsilon'_0 = 1, \quad \text{in addition to} \quad \rho^3 = {\sigma'_0}^2 = 1$$

and in such a way that these relations provide a presentation of Π (thus in particular, that $\varepsilon'_0, \sigma'_0, \rho$ generate } Π). Drawing inspiration, moreover, from the isomorphism [d2] which extends (15) and is obtained in like manner

$$(16) \qquad \mathfrak{S}_{0,3} \simeq \Pi_1 \left(U^{\mathrm{an}}_{0,3}, \underbrace{\mathfrak{S}_3 \times \mathbb{Z}/2|\mathbb{Z}_2}_{\mathcal{T}_{0,3}} \right) \longrightarrow \begin{array}{c} \mathcal{T}'_{1,1} \\ \text{cartographic group} \\ \text{triangulated non-} \\ \text{oriented} \\ \simeq \mathrm{Gl}(2,\mathbb{Z}) \end{array}$$

we should find on the first side three generators|generators $\tau'_0, \tau'_1, \tau'_\infty$ (corresponding to the analogous generators $\sigma_0, \sigma_1, \sigma_\infty$ of the corresponding|corresponding cartographic groups) satisfying|satisfying

$$(17) \qquad {\tau'_0}^2 = {\tau'_1}^2 = {\tau'_\infty}^2 = 1, \quad \left(\begin{array}{c} \underbrace{\tau'_{0|\infty}\tau'_\infty} \\ \text{corresponding to} \\ l'_1 \end{array} \right)^2 = \left(\begin{array}{c} \underbrace{\tau'_1\tau'_0} \\ \text{corresponding to} \\ l'_\infty \end{array} \right)^3 = 1$$

in such a way that these are [d3] some defining relations for $\mathfrak{S}_{0,3}$. It would be necessary that [d4] we have[i2]

$$(18)\qquad \begin{array}{ccccccccc} \tau'_\infty\tau'_1 & = & \varepsilon'_0; & & \tau'_0\tau'_\infty & = & \sigma'_0, & & \tau'_1\tau'_0 & = & \rho \\ & & \updownarrow & & & & \updownarrow & & & & \updownarrow \\ & & l'_0 & & & & l'_1 & & & & l'_\infty \end{array}$$

Scans 11–20

[scan 11]

X topological surface

$\mathcal{G}$ discrete group operating on X

G invariant subgroup of $\mathcal{G}$, operating properly on X, so that [d1] the[i1] stabilizers G_x $(x \in X)$ operate faithfully in a neighborhood of x, while preserving the local orientation at x

$Y = X/G$ (topological surface), $f\colon X \to Y$

$X^!$ discrete subset|subset of X, stable under $\mathcal{G}$,

d_X "signature" on X with support $X^!$, invariant under $\mathcal{G}$

$$i \mapsto d_X(i) \qquad X^! \longmapsto \mathbb{N}$$

$Y^! \simeq X^!/G \subset Y$ image of $X^!$ in Y

We assume $x \in X$, $G_x \neq \{1\} \;\Rightarrow\; x \in X^!$

$$d_Y\colon Y^! \to \mathbb{N}, \qquad d_Y(y) = \nu_x d_X(x)$$
$$\text{if } y = f(x), \quad \nu_x = [G_x]$$

$\mathrm{Rev}(X, d_X, \mathcal{G})$ category of ramified $\mathcal{G}$-coverings of X, subordinate to d_X

$\mathrm{Rev}(Y, d_Y, \mathcal{H})$ category of ramified $\mathcal{H}$-coverings of Y, subordinate to d_Y

For $X' \in \mathrm{Ob}\,\mathrm{Rev}(X, d_X, \mathcal{G})$, let us consider X'/G as a surface on which $\mathcal{H} = \mathcal{G}/G$ operates, over $Y = X'/G|X/G$. Then 10

[scan 12]

[p. 294]

a) $X'/G \in \operatorname{Ob} \operatorname{Rev}(Y, d_Y, \mathcal{H})$

b) We thus find|give a functor

$$\operatorname{Rev}(X, d_X, \mathcal{G}) \longrightarrow \operatorname{Rev}(Y, d_Y, \mathcal{H}) \tag{19}$$

c) This functor is an equivalence of categories.

d) Description of a quasi-inverse functor by "normalized" inverse image.

Remarks. We may assume d_X with values > 0 i.e. d_Y with values > 0 (otherwise, if $S = \{x \in X^! \mid d_X(x) = 0\}$, let us replace X by $X \setminus S$), Y by $Y \setminus T$ ($T = S/G$).

We may assume $d_X(x) = 1 \;\Rightarrow\; [G_x] \neq 1$ (otherwise, replace $X^!$ by $X^! \setminus S$ $S = \{x \in X^! \mid d_X(x) = 1,\ [G_x] = 1\}$)[i1]

The most interesting case for us is the one where [d1] $\forall x \in X^!$, we have $d_X(x) = 1$ and $G_x \neq \{1\}$ (thus $X^! = \{x \in X \mid G_x \neq \{1\}\}$), thus|in the case where

$$\operatorname{Rev}(X, d_X, \mathcal{G}) = \operatorname{Rev}(X, \mathcal{G}) \tag{20}$$

and where $\operatorname{Rev}(\dagger Y, d_Y, \mathcal{H})$ can therefore be interpreted as a $\operatorname{Rev}(X, \mathcal{G})$ (without ramification data) 11

[scan 13]

Corollary Let $x \in X \setminus X^!$, y its image in $Y \setminus Y^!$, we have a canonical isomorphism

$$\Pi_1((X, d_X, \mathcal{G}), |;x) \xrightarrow{\sim} \Pi_1((Y, d_Y, \mathcal{H}), |;y) \tag{21}$$

We are going to make explicit this isomorphism in terms of calculations of [d1]paths[i1].

An elementα[i2] of $\Pi_1((X, d_X, \mathcal{G}), |;x)$ comes from a pair (γ, ℓ), with

$$\gamma \in \mathcal{G}, \qquad \ell \text{ class of paths in } X \setminus X^! \text{ from } x \text{ to } \gamma^{-1}x$$

(with|for (γ, ℓ) and (γ', ℓ') define the same element, iff|sss $\gamma' = \gamma$, and the element[i3] $\ell'^{-1}\ell$ of $\Pi_1(X \setminus X^!, x)$ is in the invariant subgroup kernel of

$$\Pi_1(X \setminus X^!, x) \longrightarrow \Pi_1((X, d_X), x)$$

– i.e. the invariant subgroup generated by the [d2] $\lambda_a^{d_X(a)}$, where for every $a \in X^!$, λ_a denotes the class in $\Pi_1(X \setminus X^!, x|a)$ of a "loop from x around a").

Then let $\dot\gamma$ be the image of $\mathcal{G}$ in $\mathcal{H}$ – [d3] let f_U: $X \setminus X^! \overset{\text{df|def}}{=} U \longrightarrow Y \setminus Y^! \overset{\text{df|def}}{=} V \simeq U/G$ be the map 12

[p. 295]

which is canonical, then the image β[i1] of $\alpha \in \Pi_1(X, d_X, \mathcal{G}; x)$ defined by[i2] (γ, ℓ) [d1] in $\Pi_1(Y, d_Y, \mathcal{H}; y)$ is $(\dot\gamma, f_U(\ell))$

(N.B. $f_U(\ell)$ is a class of paths in $V = Y \setminus Y^!$ from $y = f_U(x)$ to $\dot\gamma^{-1}(y) = f_U(\gamma^{-1}x)$).

N.B.[i3] We see at once that if (γ, ℓ) and (γ', ℓ') define the same α, then they also define the same β, which comes from the fact that

$$\Pi_1(f_U, a) : \Pi_1(X \setminus X^!, x) \longrightarrow \Pi_1(Y \setminus Y^!, y)$$

maps a λ_a into a[i4] $\lambda_b^{\nu(a)}$ $(b = f(a)$, $\nu(a) = [G_a]$ = degree of ramification of f at $a)$ hence $\lambda_a^{d_X(a)}$ into $\lambda_b^{d_X(a)\nu(a)=d_Y(b)}$.

Let us return to the situation of (13)

$$X = U_{0,3}^{\text{an}}, \quad \mathcal{G} = \mathcal{T}_{0,3} = \mathfrak{S}_3 \times \mathbb{Z}/2, \quad G = \mathcal{T}_{0,3}^{+} = \mathfrak{S}_3$$

To calculate $\Pi_1(Y, \underline{d}_Y, \mathbb{Z}/2\mathbb{Z}) = \widetilde{\Pi}'_{0,3}$ (carto-graphic triangulated unoriented group), we took the base point $y = -\bar{j}$, so we are going to choose an $x \in U^{\mathrm{an}}_{0,3}$ over y, such that

$$f(x) = y = -\bar{j}$$

— there is d1 a[i1] choice in a set $f^{-1}(\{y\})$ with six elements, of which three in the northern hemisphere (the other three in the southern hemisphere), these are permuted transitively by ρ. They lie respectively in the spherical triangles $(-\bar{j}, 0, \frac{1}{2})$, $(-\bar{j}, 1, 2)$, $(-\bar{j}, \infty, -1)$ (mapped by f homeomorphically onto the upper spherical triangle $(0, 1, \infty)$, in the upper hemisphere)[i2] with center $-\bar{j}$). The choice of $x|a$ thus amounts to the choice of one of the three spherical triangles, or again of the 3[i3] spherical segments $(0, \frac{1}{2})$, $(1, 2)$, $(\infty, -1)$ — I feel like taking $(0, \frac{1}{2})$, corresponding to the triangle $(-\bar{j}, 0, \frac{1}{2})$.

The three involutive[i4] generators d2 $\tau'_0, \tau'_1, \tau'_\infty$ of $\Pi_1(Y, d_Y, \mathbb{Z}/2\mathbb{Z}|\mathbb{Z}/2)$ over|over $\tau \in \mathbb{Z}/2\mathbb{Z}$ are obtained by taking paths $\ell'_0, \ell'_1, \ell'_\infty$ from north pole[i5] $y = -\bar{j}$ to the south pole[i6] $\tau y = -j$, which are the|some great circle arcs crossing the equator resp. at $2, -1, \frac{1}{2}$. 14

[p. 296]

These paths are the images under f of paths on X, let them be $\lambda_0 : \overrightarrow{x, z_0}$, $\lambda_1 : \overrightarrow{x, z_1}$, $\lambda_\infty : \overrightarrow{x, z_\infty}$, which each[i3] cross the barycentric subdivision of the double spherical triangle $(0, 1, \infty)$ in exactly one point, situated respectively on the side $(\frac{1}{2}, -\bar{j})$, $(-\bar{j}, 0)$ and $(0, \frac{1}{2})$ of the spherical triangle $(0, \frac{1}{2}, -\bar{j})$.
m656

Marginal note. [m656] N.B. The points z_0, z_1, z_∞ are characterized resp.[t i4] as the only points of X over $-j = f(\dot{\tau}|\tau x)$, lying in|in the spherical triangles $(-\bar{j}, \frac{1}{2}, 1)$, $(0, -\bar{j}, -1)$, $(\frac{1}{2}, 0, -j)$.

The points [d1] z_0, z_1, z_∞ over τy are respectively of the form $g_0 x = \dot{\sigma}_\infty \dot{\tau} x$, $g_1 x = \dot{\sigma}_0 \dot{\tau} x$, $g_\infty x = \dot{\tau} x$ (i.e. $g_0 = \dot{\sigma}_\infty \dot{\tau}$, $g_1 = \dot{\sigma}_0 \dot{\tau}$, $g_\infty = \dot{\tau}$)[i8]. Thus the involutive generators $\tau'_0, \tau'_1, \tau'_\infty$ of $\widetilde{\Pi}'_{0,3} = \Pi_1(Y, d_Y, \mathbb{Z}/2\mathbb{Z}; y)$ are the images of the elements [d3], (denoted by the same sign)

$$\tau'_0 = (\dot{\sigma}_0 \dot{\tau}, \lambda_0); \quad \tau'_1 = (\dot{\sigma}_1 \dot{\tau}, \lambda_1), \quad \tau'_\infty = (\dot{\sigma}_\infty \dot{\tau}, \lambda_\infty)$$

of $\Pi_1(X, \mathcal{G}; x)$. We are going to use the great circle arc ℓ[i9] from [d4] $-\bar{j} = P$ ([d5] base point[i10] usual|usual for the calculation of $\Pi_1(X, \mathcal{G})$) to x[i11], to identify $\Pi_1(X, \mathcal{G}; x)$ with $\Pi_1(X, \mathcal{G}; P)$.

We can then take [d6]

$$\tau'_0 = (\dot{\sigma}_0 \dot{\tau}, \lambda'_0), \quad \tau'_1 = (\dot{\sigma}_1 \dot{\tau}, \lambda'_1), \quad \tau'_\infty = (\dot{\sigma}_\infty \dot{\tau}, \lambda'_\infty) \tag{21}$$

where $\lambda'_0, \lambda'_1, \lambda'_\infty$ are the [d7] [d8] paths from[i12] [d9] from $P = -\bar{j}$ to [d10] $g_i P | \dot{g}_i P$ [d11i13] [d12] 15

[p. 297]

In summary, with the notations of [C] [d1] page 7 and following, we shall therefore have

$$\begin{cases} \tau'_0 = \tilde\sigma_\infty & (\text{over } \dot\sigma_\infty\dot\tau) \\ \tau'_1 = \tilde\sigma_0 & (\text{over } \dot\sigma_0\dot\tau) \\ \tau'_\infty = \tau_\infty & (\text{over } \dot\tau) \end{cases} \tag{22}$$

N.B. $\tau_\infty = \sigma_\infty\tilde\sigma_\infty = \tilde\sigma_\infty\sigma_\infty$

We must check the essential relations

$$\tau_0'^2 = \tau_1'^2 = \tau_\infty'^2 = \big(\underbrace{\tau'_0\tau'_\infty}_{\sigma_\infty}\big)^2 = \big(\underbrace{\tau'_1\tau'_0}_{\rho^{-1}}\big)^3 = 1 \tag{23}$$

the first four are clear, the last reads

$$(\tilde\sigma_0\tilde\sigma_\infty)^3 = 1$$

now we have

$$\tilde{\sigma}_0\tilde{\sigma}_\infty = \rho^{-1} \qquad ([C],\ \text{formula 13,})$$

whence what we want.

Let us compute (in accordance with (18)) $\tau'_\infty\tau'_1$, $\tau'_0\tau'_\infty$, $\underbrace{\tau'_1\tau'_0}_{\rho^{-1}}$ — which will have to correspond to $\ell'_0, \ell'_1, \ell'_\infty$ —

$$\ell'_0 = \tau'_\infty\tau'_1 = \tau_\infty\tilde{\sigma}_0 = \sigma_\infty\underbrace{\tilde{\sigma}_\infty\tilde{\sigma}_0}_{\rho} = \sigma_\infty\rho$$
$$\ell'_1 = \tau'_0\tau'_\infty = \sigma_\infty$$
$$\ell'_\infty = \tau'_1\tau'_0 = \rho^{-1}$$

i.e.

$$\ell'_0 = \sigma_\infty\rho, \quad \ell'_1 = \sigma_\infty, \quad \ell'_\infty = \rho^{-1} \tag{24}$$

with the characteristic relations

$$\ell'_\infty\ell'_1\ell'_0 = 1, \qquad \ell'^{\,2}_{1|\infty} = 1, \qquad \ell'^{\,3}_\infty = 1 \tag{25}$$

Everything is OK!

m660

Marginal note. m660 We express the distinguished elements $\rho, \sigma_0, \sigma_1, \sigma_\infty, \ell_0, \ell_1, \ell_\infty, \tau_0, \tau_1, \tau_\infty$ of $\Pi_1(U^{\mathrm{an}}_{0,3}; \mathfrak{S}_3 \times \mathbb{Z}/2)$ in terms of the $\tau'_0, \tau'_1, \tau'_\infty$ as follows:

$$\rho = \tau'_0\tau'_1$$
$$\tau_\infty = \tau'_\infty, \quad \tau_0 = \rho\tau_\infty\rho^{-1} = \tau'_0\tau'_1\tau'_\infty\tau'_1\tau'_0,$$
$$\tau_1 = \rho^{-1}\tau_\infty\rho = \ldots = \tau'_1\tau'_\infty\tau'_1$$

$= \tau'_\infty\tau'^{\,i2}_0$

$$\sigma_\infty = \tau'_0\tau'_\infty, \quad \sigma_0 = \rho\sigma_\infty\rho^{-1} = \tau'_0\tau'_1\tau'_0\tau'_\infty\tau'_1\tau'_0,$$
$$\sigma_1 = \rho^{-1}\sigma_\infty\rho = \tau'_1\tau'_\infty\tau'_0\tau'_1$$
$$\ell_0 = \tau_\infty\tau_1 = \tau'_\infty\tau'_1\tau'_\infty\tau'_1 = (\tau'_\infty\tau'_1)^2$$
$$\ell_1 = \tau_0\tau_\infty = \tau'_0\tau'_1\tau'_\infty\tau'_1\tau'_0\tau'_\infty$$
$$\ell_\infty = \tau_1\tau_0 = (\underbrace{\tau'_1\tau'_\infty\tau'_1}\,\tau'_0)^2$$
$$\varepsilon_0 = \ell'_0 = \tau'_\infty\tau'_1$$
$$\varepsilon_1 = \tau'_0\tau'_1\tau'_\infty\tau'_0$$
$$\varepsilon_\infty = \tau'_1\tau'_\infty\tau'_1\tau'_0$$

[scan 19]

I would also like to make explicit the relation of $\widetilde{\Pi}'_{0,3}$ unoriented carto-graphic group[i1] $\simeq \mathfrak{S}_{0,3}$ $= \mathrm{Aut}_{\mathrm{loc|ext}}(\Pi_{0,3})$[i2] with $\mathrm{GP}(1,\mathbb{Z}) \simeq \mathrm{Gl}(2,\mathbb{Z})' \overset{\text{def}}{=} \mathrm{Gl}(2,\mathbb{Z})/\{\pm 1\}$. Let us first recall the operation of

$$\mathrm{GP}(1,\mathbb{R}) \simeq \mathrm{Gl}(2,\mathbb{R})/\mathbb{R}^* \simeq \mathrm{Gl}(2,\mathbb{R})^{\pm 1}/\{\pm 1\} \tag{26}$$

on the Poincaré half-plane D

$$D = \{z \in \mathbb{C} \mid \Im(z) > 0\} = \{x + iy \mid x \in \mathbb{R}, y \in \mathbb{R}^{*+}\}. \tag{27}$$

We make the matrix $u = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ operate by

$$f_u(z) = \begin{cases} \dfrac{az+b}{cz+d} & \text{if } \det u > 0 \\ \dfrac{a\bar{z}+b}{c\bar{z}+d} & \text{if } \det u < 0 \end{cases} \tag{28}$$

In this way, $\mathrm{GP}(1,\mathbb{R})$ is isomorphic to the group of conformal automorphisms of D.

m662

Marginal note. [m662] N.B. $\mathrm{GP}(1,\mathbb{R})$ has two connected components. Its identity component $\mathrm{GP}(1,\mathbb{R})^{+}$[i3] is the image of $\mathrm{Sl}(2,\mathbb{R})$ (or of|of $\mathrm{Gl}(2,\mathbb{R})^{+}$) and is identified with $\mathrm{Sl}(2,\mathbb{R})/\pm 1$.

Moreover, the datum of an elliptic curve E[i4] over $\mathbb{C}$ is equivalent to that of a space V of dimension 1 over $\mathbb{C}$, and of a "lattice" $\pi \subset V$ (discrete subgroup of rank 2). The canonical orientation of V corresponds to a generator $\eta|\gamma$ of $\bigwedge^2_{\mathbb{Z}} \pi$ — thus π is "oriented". The choice of a rigidification

equivalence of categories [illeg. 1].

[scan 20]

[p. 298]

of unimodular Jacobi type for π, is equivalent to that of a basis (e_1, e_2) of π (as a $\mathbb{Z}$-module)[i1] such that $e_1 \wedge e_2 = \eta|\gamma$. The element e_1 (as a basis of V over $\mathbb{C}$)[i2] moreover allows us to identify V with $\mathbb{C}$, e_1 becoming 1. Thus the datum of E with its unimodular Jacobi rigidification, is equivalent to that of an element $e_2 = \tau$ of $\mathbb{C}|E$, such that

1°) $(1,\tau)$ generate|generates a discrete subgroup of rank 1, i.e. $\tau \notin \mathbb{R}$ i.e. $\Im\tau \neq 0$

2°) the orientation of the said subgroup defined by the basis $(1,\tau)$ is "positive", i.e. $\Im\tau > 0$, i.e. $\tau \in D$.

When we look at the operation of $\mathrm{Sl}(2,\mathbb{Z})$ on the set[i3] of isomorphism classes of rigidified elliptic curves, set identified with D, we find that $\begin{pmatrix} a, b \\ c, d \end{pmatrix}$ operates by $\tau \longmapsto \dfrac{a\tau + b}{c\tau + d}$, i.e. it is the natural operation of $\mathrm{Sl}(2,\mathbb{Z})$ on D, through $\mathrm{Sl}(2,\mathbb{Z})' \simeq \mathrm{GP}(1,\mathbb{Z})^+$.

This group operates properly, It has exactly two critical orbits, which corres- 19

[p. 299]

39 d1The i1 congruence conditions for the outer operation of $\Gamma_{\mathbb{Q}}$ on $\widehat{\Pi}_{0,3}$.
Let us consider the diagram

$$\begin{array}{ccccccccc} 1 & \longrightarrow & \widehat{\mathcal{T}}^{+}_{1,1} & \longrightarrow & N_{1,1} & \longrightarrow & \Gamma_{\mathbb{Q}} & \longrightarrow & 1 \\ & & \wr & & & & & & \\ & & \mathrm{Sl}(2,\mathbb{Z})^{\wedge} & & \downarrow & & \downarrow \chi & & \\ & & \downarrow & & & & & & \\ 1 & \longrightarrow & \mathrm{Sl}(2,\widehat{\mathbb{Z}}) & \longrightarrow & \mathrm{Gl}(2,\widehat{\mathbb{Z}}) & \xrightarrow{\det} & \widehat{\mathbb{Z}}^{*} & \longrightarrow & 1 \end{array} \tag{1}$$

It shows that the outer operation of $\Gamma_{\mathbb{Q}}$ on $\widehat{\mathcal{T}}^{+}_{1,1} \simeq \mathrm{Sl}(2,\mathbb{Z})^{\wedge i2}$ passes to the|to the quotient as an outer action on $\mathrm{Sl}(2,\widehat{\mathbb{Z}})$, and this outer action, moreover, can be made entirely explicit with the help of the cyclotomic character

$$\chi : \Gamma_{\mathbb{Q}} \longrightarrow \widehat{\mathbb{Z}}^{*}. \tag{2}$$

To make this last point precise, let us note that the second row of (1) gives a homomorphism

$$\widehat{\mathbb{Z}}^{*} \longrightarrow \mathrm{Autext}(\mathrm{Sl}(2,\widehat{\mathbb{Z}})), \tag{3}$$

and the canonical homomorphism

$$\Gamma_{\mathbb{Q}} \longrightarrow \mathrm{Autext}(\mathrm{Sl}(2,\widehat{\mathbb{Z}})) \tag{4}$$

[scan 24]

[p. 300]

the kernel of (4) is none other than the kernel of the composite

$$\Gamma_{\mathbb{Q}} \xrightarrow{\chi} \widehat{\mathbb{Z}}^* \longrightarrow \widehat{\mathbb{Z}}^*/\widehat{\mathbb{Z}}^{*2} \tag{6}$$

i.e. (by class field theory for $\mathbb{Q}$) the outer[i1] operation of $\Gamma_{\mathbb{Q}}$ on $\mathrm{Sl}(1|2, \widehat{\mathbb{Z}})$ factors through an outer[i2] operation of $(\Gamma_{\mathbb{Q}\,\mathrm{ab}})_2$ – the "multiquadratic" quotient of $\Gamma_{\mathbb{Q}}$ – and the latter is faithful.

m671

Marginal note. [m671] N.B. The outer operation of $\Gamma_{\mathbb{Q}}$ on $\mathrm{Sl}(2, \mathbb{Z}/n|m\mathbb{Z})$ takes place through the intermediary of $((\mathbb{Z}/n|m\mathbb{Z})^*)_2|(\mathbb{Z}/n|m\mathbb{Z})^*_2$

Thus, if we identify $\Gamma_{\mathbb{Q}}$ [d1] with a subgroup of $\mathrm{Autext}\,\mathrm{Sl}(2, \widehat{\mathbb{Z}})^\wedge$, this subgroup Γ[i3] is subject to fairly strong conditions : [d2] leave invariant the normal subgroup kernel of

$$\mathrm{Sl}(2, \mathbb{Z})^\wedge \longrightarrow \mathrm{Sl}(2, \widehat{\mathbb{Z}}) \tag{7}$$

and induce on $\mathrm{Sl}(2, \widehat{\mathbb{Z}})$ [d3]an[i4] outer operation coming from a homomorphism $\Gamma \longrightarrow \widehat{\mathbb{Z}}^*/\widehat{\mathbb{Z}}^{*2}$. We can moreover make this homomorphism precise as follows. Let us consider in $\mathrm{Sl}(2, \widehat{\mathbb{Z}})$ the "loop-subgroup" coming from the point at 23

of $\Gamma_{\mathbb{Q}}$ on $\widehat{\mathcal{T}}^+_{1,1}$ does not allow us a priori to reconstruct (up to unique isomorphism) the extension $N_{1,1}$ of $\Gamma_{\mathbb{Q}}$ by $\widehat{\mathcal{T}}^+_{1,1}$ of (1). It gives only the extension [d1] $N'_{1,1}$ of $\Gamma_{\mathbb{Q}}$ by

$$\widehat{\mathcal{T}}^{+\prime}_{1,1} \simeq \mathrm{Sl}(2,\mathbb{Z})^\wedge/\{\pm 1\} \overset{\text{dfn|déf}}{=} \mathrm{Sl}(2,\widehat{\mathbb{Z}})'$$

(by inverse image of the extension

$$(13)\quad 1 \to \mathrm{Sl}(2,\widehat{\mathbb{Z}})' \to \mathrm{Aut}_{\mathrm{lac}}(\mathrm{Sl}(2,\mathbb{Z})^\wedge) \to \mathrm{Autext}_{\mathrm{lac}}\ \mathrm{Sl}(2,\mathbb{Z})^\wedge \downarrow 1$$

This extension $N'_{1,1}$[i2] has also been interpreted as the extension $M_{0,3} \simeq N'_{0,4}$ of $\Gamma_{\mathbb{Q}}$ by $\widehat{\mathfrak{S}}_{0,3} \simeq \widehat{\mathcal{T}}'_{0,4}$ (group which is itself an extension of $\mathfrak{S}_3 \simeq \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z})$ by $\widehat{\Pi}_{0,3}$). We already know that the outer[i3] operation of $\Gamma_{\mathbb{Q}}$ on the kernel $\widehat{\Pi}_{0,3}$ of $\mathrm{Sl}(2,\overset{\dagger|\wedge}{\mathbb{Z}})^{\wedge\prime} \longrightarrow \mathrm{Sl}(2,\mathbb{Z}/2|\mathbb{Z}_2)$ is faithful, and commutes with the outer operation of $\mathfrak{S}_3 \simeq \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z}) \simeq \mathrm{Sl}(2,\mathbb{Z})^{\wedge\prime}/\widehat{\Pi}_{0,3}$. But this commutation can at pres- 26

[p. 302] ent be interpreted as a consequence of the fact that the outer operation of $\Gamma_{\mathbb{Q}}$ on $\mathfrak{S}_3 \simeq \mathrm{Sl}(2, \mathbb{Z}/2\mathbb{Z})$ is trivial, itself (from the present viewpoint)[i1] a consequence of the fact that it takes place through the intermediary of a (faithful) operation of $(\mathbb{Z}/n\mathbb{Z})^*_{/2|2}$, now for $n = 2$ $(\mathbb{Z}/n\mathbb{Z})^*_2 = 1$ (a relation which is on the other hand false for [d1] other|other[i2] values, $n \neq 1, 2$ i.e. $n \geq 3$). This commutation relation, of a fairly trivial nature, thus appears at present as a very special case of the markedly subtler congruential relations. We can try to[i3] express them [d3] [d4] directly in terms of the outer operation of $\Gamma_{\mathbb{Q}}$ on $\widehat{\Pi}_{0,3}$, by introducing the kernels of the homomorphisms $\widehat{\mathcal{T}}^{+/|+/n}_{1,1} \longrightarrow \mathrm{Sl}(2, 2m)$, which are open subgroups [d5] :

$$\Pi(2m) \subset \widehat{\Pi}_{0,3} \qquad (14)$$

of homomorphisms

$$(15) \qquad \varphi_{2m} : \widehat{\Pi}_{0,3} \longrightarrow \mathrm{Sl}(2, \mathbb{Z}/2m)'$$

which it should of them|not be very difficult to make explicit, [d1] by "reduction modulo $2m$"[i1] of a homomorphism

$$(16) \qquad \varphi_{\infty} : \widehat{\Pi}_{0,3} \longrightarrow \mathrm{Sl}(2, \widehat{\mathbb{Z}})'$$

which has already been mentioned previously – homomorphism whose image is the kernel subgroup of $\mathrm{Sl}(2, \widehat{\mathbb{Z}})' \longrightarrow \mathrm{Sl}(2, \mathbb{Z}/2\mathbb{Z})$, i.e. we have an exact sequence

$$(17) \qquad 1 \longrightarrow \Pi(\infty) \longrightarrow \widehat{\Pi}_{0,3} \longrightarrow \mathrm{Sl}(2, \widehat{\mathbb{Z}})' \longrightarrow \mathrm{Sl}(2, \mathbb{Z}/2\mathbb{Z}) \longrightarrow 1$$

$$(18) \qquad 1 \longrightarrow \Pi(2m) \longrightarrow \widehat{\Pi}_{0,3} \longrightarrow \mathrm{Sl}(2, \mathbb{Z}/2m\mathbb{Z})' \longrightarrow \mathrm{Sl}(2, \mathbb{Z}/2\mathbb{Z}) \longrightarrow 1.$$

This being laid down, these|the exact sequences allow us in a natural way to define an outer operation of $\widehat{\mathbb{Z}}^*/\widehat{\mathbb{Z}}^{*2}$ on $\widehat{\Pi}_{0,3}/\Pi(\infty)$, or again of the $(\mathbb{Z}/2m\mathbb{Z})_2^*$ on the $\widehat{\Pi}_{0,3}/\Pi(2m)$, and the "condition of congruence|congruences" is expressed by saying that the cyclotomic character χ of $\Gamma_{\mathbb{Q}}$ (which we can regard as[i3] deduced from the outer operation of 28

[scan 31]

question whether the conditions do indeed constitute a restriction, an effective one, on an outer automorphism of the group with loops $\widehat{\Pi}_{0,3}$, commuting with the action of $\mathfrak{S}_3$, may very well be out of reach, for lack of knowing how actually to construct such outer automorphisms (one|or [illeg. 1] some nontrivial elements of $\widehat{\widehat{\mathcal{T}}}|\widehat{\mathcal{T}}^{!*}_{0,3}$)[i1] in any other way than precisely by arithmetic means, with the help of the operation of $\Gamma_{\mathbb{Q}}$ on $\widehat{\Pi}_{0,3}$! (One should all the same make another effort in this direction sometime …)

I also ask myself the question to|of what extent one can reconstruct, in terms of the theory of profinite groups with loops and of the [d1] outer automorphisms of $\widehat{\Pi}_{0,3}$, or of [d2]$\widehat{\mathfrak{S}}^{+}_{0,3}$[i2] $\simeq \widehat{\mathcal{T}}^{+\prime}_{1,1}$, [d3] 30

[p. 304]

a) the finer extension $N_{1,1}$ of $\Gamma_{\mathbb{Q}}$ by $\widehat{\mathcal{T}}^{+}_{1,1}$, which is thus an extension of $N'_{1,1}$ (supposed to be known) by the group $\{\pm 1\}$

b) the homomorphism

$$\boxed{N_{1,1} \longrightarrow \mathrm{Gl}(2, \widehat{\mathbb{Z}})} \qquad (21)$$

of (1), and failing that, the homomorphism [d1]

$$N'_{1,1} \simeq M_{0,3} \longrightarrow \mathrm{Gl}(2,\widehat{\mathbb{Z}})/\{\pm 1\}. \tag{22}$$

I will begin|begin with question b).

If one has the extension $N_{1,1}$ of $\Gamma_{\mathbb{Q}}$ by $\widehat{\mathcal{T}}^{+}_{1,1} \simeq \mathrm{Sl}(2,\mathbb{Z})^{\wedge}$, one has a homomorphism

$$N_{1,1} \longrightarrow \mathrm{Aut}_{\mathrm{lac}}\left(\underbrace{\widehat{\mathcal{T}}^{+}_{1,1}}_{\mathrm{Sl}(2,\mathbb{Z})^{\wedge}}\right) \tag{23}$$

which passes to the quotient as a homomorphism

$$N_{1,1} \longrightarrow \mathrm{Aut}_{\mathrm{lac}}\left(\mathrm{Sl}(2,\widehat{\mathbb{Z}})\right) \tag{24}$$

now one has an obvious homomorphism

$$\mathrm{Gl}(2,\widehat{\mathbb{Z}}) \longrightarrow \mathrm{Aut}_{\mathrm{lac}}\left(\mathrm{Sl}(2,\widehat{\mathbb{Z}})\right)$$

which factors as

$$\mathrm{Gl}(2,\widehat{\mathbb{Z}}) \longrightarrow \mathrm{Gl}(2,\widehat{\mathbb{Z}})/\widehat{\mathbb{Z}}^{*} \simeq \mathrm{GP}(1,\widehat{\mathbb{Z}}) \hookrightarrow \mathrm{Aut}_{\mathrm{lac}}\left(\mathrm{Sl}(2,\widehat{\mathbb{Z}})\right) \tag{25}$$

and it turns out that (24) factors as

$$N_{1,1} \longrightarrow \underset{\simeq \mathrm{Gl}(2|1,\widehat{\mathbb{Z}})/\widehat{\mathbb{Z}}^{*}}{\mathrm{GP}(1,\widehat{\mathbb{Z}})} \hookrightarrow \mathrm{Aut}_{\mathrm{lac}}\left(\mathrm{Sl}(2,\widehat{\mathbb{Z}})\right) \tag{26}$$

[scan 33]

which thus makes it possible to reconstruct, from the extension $N_{1,1}$, a homomorphism

$$N_{1,1} \overset{\varphi}{\to} \mathrm{GP}(1,\widehat{\mathbb{Z}}) \simeq \mathrm{Gl}(2,\widehat{\mathbb{Z}})/\widehat{\mathbb{Z}}^{*}, \tag{27}$$

a little weaker than the homomorphism (21) we are trying to construct. But let us note that the homomorphism

$$\begin{array}{ccc} \mathrm{Gl}(2,\widehat{\mathbb{Z}}) & \xrightarrow{u\mapsto(\dot{u},\det(u))} & \mathrm{GP}(1,\widehat{\mathbb{Z}}) \quad \times \widehat{\mathbb{Z}}^{*} \\ & & \downarrow \\ & & \widehat{\mathbb{Z}}^{*}/\widehat{\mathbb{Z}}^{*2} \end{array} \tag{28}$$

has as its kernel the set of $\lambda \in \widehat{\mathbb{Z}}^*$ such that $\lambda^2 = 1$ – i.e. the group

$$ {}_2\widehat{\mathbb{Z}}^* \simeq (\mathbb{Z}/2\mathbb{Z})^P \tag{29} $$

P= | : set of prime numbers

Thus, one finds that the homomorphism

$$ N_{1,1} \xrightarrow{u \mapsto (\varphi(u), \chi(u))} \mathrm{GP}(1, \widehat{\mathbb{Z}}) \times \widehat{\mathbb{Z}}^* \tag{30} $$

(deduced from (27) and from χ) § [m683]

Marginal note. [m683] this is yet another condition on the extension $N_{1,1}$ of $\Gamma_{\mathbb{Q}}$ by $\widehat{\mathcal{T}}^+_{1,1}$, i.e. [illeg. 1] of the outer operation of $\Gamma_{\mathbb{Q}}$ on $\widehat{\mathcal{T}}^+_{1,1}$

factors through the image of (28), and thus defines a homomorphism

$$ N_{1,1} \xrightarrow{\psi} \mathrm{Gl}(2, \widehat{\mathbb{Z}})/{}_2\widehat{\mathbb{Z}}^* \tag{31} $$

which is still a weakened version of (21). 32

[scan 34]

[p. 305]

In fact, the homomorphism (31) factors as

$$ [N_{1,1} \longrightarrow] \; \underset{\| \; N_{1,1}/\pm 1}{N'_{1,1}} \xrightarrow{\psi'} \mathrm{Gl}(2, \widehat{\mathbb{Z}})/{}_2\widehat{\mathbb{Z}}^* \tag{31} $$

and the homomorphism ψ' can surely be constructed directly from the extension $N'_{1,1}$ of $\Gamma_{\mathbb{Q}}$ by $\widehat{\mathcal{T}}^{+\prime}_{1,1} \simeq \widehat{\mathfrak{S}}^+_{0,3} \simeq \mathrm{Sl}(2, \widehat{\mathbb{Z}})'$[i1], just as ψ a moment ago: it suffices to check that the canonical homomorphism

$$ \underset{\wr \; \mathrm{Gl}(2,\widehat{\mathbb{Z}})/\widehat{\mathbb{Z}}^*}{\mathrm{GP}(1, \widehat{\mathbb{Z}})} \longrightarrow \mathrm{Aut}_{\mathrm{lac}}(\mathrm{Sl}(2, \widehat{\mathbb{Z}})') \tag{33} $$

is again[i2] injective. The question here[i3] (in terms of the theory of profinite groups…)[i4] how to [d1]make explicit the lifting of[i5] ψ' of (31) to the canonical homomorphism

$$ N'_{1,1} \longrightarrow \mathrm{Gl}(2, \widehat{\mathbb{Z}})' \overset{\mathrm{dfn}}{=} \mathrm{Gl}(2, \widehat{\mathbb{Z}})/\pm 1 \tag{34} $$

— once this homomorphism has been obtained, one deduces from it the extension $N_{1,1}$ by inverse image of the extension structure

$$ 1 \longrightarrow \{\pm 1\} \longrightarrow \mathrm{Gl}(2, \widehat{\mathbb{Z}}) \longrightarrow \mathrm{Gl}(2, \widehat{\mathbb{Z}})' \longrightarrow 1, \tag{35} $$

as well as the homomorphism (21) $N_{1,1} \longrightarrow \mathrm{Gl}(2, \widehat{\mathbb{Z}})$. 33

[scan 35]

So in summary, the essential question here seems to be the determination of the lifting (34) of (32).

Let us take up our arguments again. We take a subgroup Γ of $\mathrm{Autext}_{\mathrm{lac}}(\widehat{\Pi}_{0,3})$, commuting with $\mathfrak{S}_3$, whence an extension [d1] (denoted $M_{0,3}$ or $N'_{1,1}$) of Γ by $\widehat{\mathfrak{S}}^{+}_{0,3}$, or again of $\mathfrak{S}_3 \times \Gamma$ by $\widehat{\Pi}_{0,3}$, [d2] whence a[i1] homomorphism

$$M_{0,3}(N'_{1,1})|(=N'_{1,1}) \longrightarrow \mathrm{Aut}_{\mathrm{lac}}\left(\underbrace{\widehat{\mathfrak{S}}^{+}_{0,3}}_{\mathrm{Sl}(2,\widehat{\mathbb{Z}}|\mathbb{Z})'^{\wedge}}\right) \tag{36}$$

inducing on $\widehat{\mathfrak{S}}^{+}_{0,3}$ [d3]the operation[i2] of this group on itself that is inner. One has, moreover, an injective homomorphism

$$\mathrm{GP}(1,\widehat{\mathbb{Z}}) \hookrightarrow \mathrm{Aut}(\mathrm{Sl}(2,\widehat{\mathbb{Z}})') \tag{37}$$

and $\Gamma \subset \mathrm{Autext}_{\mathrm{lac}}(\widehat{\Pi}_{0,3})$ is subject (unless this is already[i3] a consequence of the hypothesis of commutation with $\mathfrak{S}_3$) to the condition that the outer[i4d4] homomorphism

$$\underset{\mathrm{Sl}(2,\mathbb{Z})'^{\wedge}}{\widehat{\mathfrak{S}}^{+}_{0,3}} \longrightarrow \mathrm{Sl}(2,\widehat{\mathbb{Z}})' \tag{38}$$

[scan 38]

[p. 307] sole datum of $\Gamma \subset \mathrm{Autext}_{\mathrm{lac}}(\widehat{\Pi}_{0,3})$, satisfying the congruential conditions stated above?

Let us note that on the subgroup $\widehat{\mathcal{T}}^+_{0,3} \simeq \mathrm{Sl}(2, \widehat{\mathbb{Z}}|\mathbb{Z})'^{\wedge}$ of $M_{0,3}$, the [d2]lifting[i1] sought (47) is already known, as being

$$\mathrm{Sl}(2,\mathbb{Z})'^{\wedge} \longrightarrow \mathrm{Sl}(2,\widehat{\mathbb{Z}})' \hookrightarrow \mathrm{Gl}(2,\widehat{\mathbb{Z}})'.$$

In other words, the sought-for splitting of (46) is already known over the subgroup $\widehat{\mathcal{T}}^+_{0,3}$ of $M_{0,3}$.

The indeterminacy of the liftings or splittings being a priori in [d3]

$$\mathrm{Hom}(M_{0,3}, \underline{\nu|V}),$$

taking account of the preceding condition, it will be in

$$(48) \qquad \begin{aligned} \mathrm{Ker}(\mathrm{Hom}(M_{0,3}, \underline{\nu|V}) &\longrightarrow \mathrm{Hom}(\widehat{\mathcal{T}}^+_{0,3}, \underline{\nu|V})) \\ &\simeq \mathrm{Hom}(\Gamma, \nu|V) - \end{aligned}$$

if one assumes that $\Gamma/\Gamma_{\mathrm{ab}} \xrightarrow{\chi} \widehat{\mathbb{Z}}^*$ is an isomorphism, the indeterminacy would still be in $\mathrm{Hom}((\widehat{\mathbb{Z}}^*)_2, \nu|V)$ — that's big ! It 37

takes a somewhat clever element to justify this lifting — one guesses that it is linked precisely to the interpretation of an $M_{0,3}$ as an $N'_{1,1}$ — i.e. to the introduction, into a "profinite theory of|of the rational curves", of the "profinite theory of elliptic curves".

---

40 Topologico-isotopic|Topologico-isotopic[i1] paraphrase (in terms of fundamental groups) of the Theory of Legendre

To feel out the terrain, I feel like starting first from the situation of discrete groups, which we have better in hand, one can well say so !

Let $C_{0,3}$ be the category of (discrete) groups with loops of type $0, 3$ (with isomorphisms as arrows)[i2], whose standard representative is $\Pi_{0,3}$ — this category is therefore canonically equivalent to that of torsors under the group

$$\text{(49)} \qquad \mathrm{Aut}_{\mathrm{lac}}(\Pi_{0,3}) \simeq \mathfrak{S}_{0,3} \simeq \mathrm{Gl}(2,\mathbb{Z})^{\wedge}/\pm 1 \simeq \mathrm{GP}(1,\mathbb{Z})$$

Let $C^{\mathrm{ext}}_{1,1}$ be the category of outer[i3] groups with loops of type $(1,1)$, [d1]whose[i4] standard representative is $\Pi_{1,1} = \{x, y, l \mid [x,y]l = 1\}$; this category is 38

[scan 42]

[p. 309] In short, I am in the process of making a topological isotopic paraphrase, in terms of the fundamental groups with loops, of Legendre's theory of the relations between elliptic curves and rational curves. I would like now to make explicit the Legendre equivalence (55), which had been obtained thanks to the knowledge of the appropriate Teichmüller groups relative to the two sides and of an ad-hoc isomorphism between these two groups, directly in terms of the fundamental groups of type|types $\Pi_{0,3}$ or|and $\Pi_{1,1}$.

If π' is a group with loops of type $1.1|1,1$, it is appropriate first to note that there is in $\mathrm{Autext}_{\mathrm{lac}}(\pi')$ a canonical element of order 2 — in fact the unique nontrivial element of the center — denoted as is only right $(-1)_{\pi'}$. [m693]

Marginal note. [m693] N.B. $(-1)_{\pi'}|\mathrm{Aut}_{\pi'}$ preserves the orientation i.e. has multiplier|multiplicity $+1$

[scan 43]

Thus, one can consider π' as endowed canonical[lyi1] with an [d1] outer operation of $G = \mathbb{Z}/2\mathbb{Z}$ on it, whence a canonical extension

$$(58) \qquad 1 \longrightarrow \pi' \text{ — } \mathcal{E} \longrightarrow \mathbb{Z}/2\mathbb{Z} \longrightarrow 1.$$

The topological model teaches us that there are exactly three π'- conjugacy classes of splittings of this extension, corresponding to the three points of order 2 of a topological group $E \simeq \mathbf{U} \times \mathbf{U}$ — the three fixed points of $x \mapsto -x$ in $E \setminus \{0\}$. The theory of "drilling holes simultaneously", relative to a situation of a finite[i2] group of outer operators of a|of a group with loops (theory which even in the discrete case has not really been written — for the moment there are conjectural statements) then makes it possible [m694]

Marginal note. [m694] but here, one is in a case [illeg. 2] can get by with drillings [illeg. 1] of one hole at a time, repeated successively...

with the fundamental group of

$$V = (E \setminus {}_2E)/\{\pm 1\} \tag{61}$$

which is a topological surface of type $(0, 4)$.

In other words, $\tilde{\mathcal{E}}$ can be considered as a group with loops of type $(0, 4)$, for a loop structure easy to describe in terms of that of $\tilde{\pi}'$, and for which one has a canonical isomorphism

$$I(\tilde{\mathcal{E}}) \simeq I(\tilde{\pi}')/G \simeq I(\tilde{\pi}'). \tag{62}$$

Thus one has an $i_0 \in I(\tilde{\mathcal{E}})$, which allows one to "plug the hole at i_0" to obtain an actual[i1] group with loops of type $(0, 3)$, i.e. [d1]

$$\pi = \mathcal{L}(\pi') \tag{63}$$

Taking up in the reverse direction the relation between π and π', one can proceed as follows: to an actual group with loops[i2] of type $(0, 3)$, one associates by

[scan 46]

[p. 311]

the "drilling holes" functor an outer group with loops $\tilde{\pi}(= \tilde{\mathcal{E}}| \in \tilde{\mathcal{E}})$[i1] of type $(0, 4)$, endowed with an element $i_0 \in I(\tilde{\pi})$ such that [d1]

$$I(\tilde{\pi}) \simeq \{i_0\} \amalg \underbrace{I(\pi)}_{\text{cardinality } 3} \tag{64}$$

One then has (T being the orientation module of π)

$$\tilde{\pi}_{\mathrm{ab}} \simeq T^{I(\tilde{\pi})} \qquad (\tilde{\pi}_{\mathrm{ab}})_2 \simeq (\mathbb{Z}/2\mathbb{Z})^{I(\tilde{\pi})} \tag{65}$$

and one has an (outer) homomorphism

$$\tilde{\pi} \longrightarrow \mathbb{Z}/2\mathbb{Z} \tag{66}$$

canonical, defined by the condition of being "ramified" at all the $i \in I(\tilde{\pi})$ — i.e. corresponding to the homomorphism

$$(\tilde{\pi}_{\mathrm{ab}})_2 \xrightarrow{\sim} (\mathbb{Z}/2\mathbb{Z})^{I(\tilde{\pi})} \longrightarrow \mathbb{Z}/2\mathbb{Z} \tag{67}$$

sum of the coefficients. The kernel $\tilde{\pi}'$ of (66) is a group with loops of type $(1, 4)$ — but it is not quite an outer group — it is not defined "modulo|up to inner automorphisms", [d2] only modulo (in addition) the outer operation of symmetry of $\mathbb{Z}/2\mathbb{Z}$

Apparatus for this scan

[scan 47]

on it. If one chooses the group $\tilde{\pi}$ (in its "outer class") – one will in any case have an exact sequence

$$1 \longrightarrow \tilde{\pi}' \longrightarrow \tilde{\pi} \text{ — } \mathbb{Z}/2\mathbb{Z} \longrightarrow 1 \tag{68}$$

and $\tilde{\pi}'$ is a group with loops, with

$$I(\tilde{\pi}') \simeq I(\tilde{\pi}) \tag{69}$$

By plugging the holes corresponding to $I(\pi) \subset I(\tilde{\pi}) \simeq | = I(\tilde{\pi}')$, which is of cardinality 3, one obtains a [d1] group of type $(1,1)$, with operation of $\mathbb{Z}/2\mathbb{Z}$ on it which is none other than the canonical operation[i1]. But depending on the indeterminacies of the choices made, it is a little less than an outer group of type $(1,1)$ i.e. an object of $C^{\mathrm{ext}}_{1,1}$ – it is such an element, "modulo symmetry" – i.e. an object of $C^{\mathrm{ext}\prime}_{1,1}$. To have an object of $C^{\mathrm{ext}}_{1,1}$, one must have "chosen a kernel" $\tilde{\pi}'$ for the homomorphism which is outer $\tilde{\pi} \longrightarrow | \text{ —} \mathbb{Z}/2\mathbb{Z}$, as an outer group – this is the choice of an object

in a $(\mathbb{Z}/2\mathbb{Z})$-gerbe, i.e. in[i1] a connected groupoid admitting $\mathbb{Z}/2\mathbb{Z}$ as fundamental group. 3

Modulo a more careful write-up, it seems to me that these conceptual reflections do indeed prove and without a flaw|flaws that one has a canonical isomorphism (at least modulo inner|inner automorphisms)

$$\mathcal{T}_{1,1}/\{\pm 1\} \xrightarrow{\sim} \mathfrak{S}_{0,3} \tag{70}$$

m697

Marginal note. [m697] in fact, one can make it|it precise modulo inner automorphisms arising from|from the $\mathfrak{S}^{1+|i,+}_{0,3} \simeq \Pi_{0,3}$

– the indeterminacy modulo inner automorphisms arising quite certainly from the choice of an isomorphism between $\mathcal{L}(\Pi_{1,1})$ and $\Pi_{0,3}$.

This fact is quite independent, [d1] it seems to me, of the fact that the homomorphism which is natural

$$\mathcal{T}_{1,1} \xrightarrow{\sim} \mathrm{Gl}(2,\mathbb{Z})$$

is an isomorphism. I see no objection to identifying $\mathcal{T}_{1,1}$ purely and simply with $\mathrm{Gl}(2|1,\mathbb{Z})$ on occasion,|; on the other hand it is more questionable to identify $\mathfrak{S}_{0,3}$ with $\mathcal{T}_{1,1}/\pm 1$ or with $\mathrm{Gl}(2,\mathbb{Z})'$

[p. 314] mod the kernel $\Pi(2)^{i1}$ of $\mathrm{Sl}(2|1,\mathbb{Z}) \longrightarrow \mathrm{Sl}(2,\mathbb{Z}/2\mathbb{Z})$, i.e. that they do not have the same image in $U_{0,3}^{\mathrm{an}} \simeq D/\Pi(2)$, so their images are $P = -\bar{j}$ and $\bar{P} = -j$ (or the other way around)] The choice in question is ^{d1} characterized by the fact that $\tau \in D$ above P is ^{d2} a root of unity, which is after all quite natural. One can therefore say that one has "normalized" the categorical^{i2} homomorphism (73) into an actual homomorphism – and by the same token also (70).

One would like to take up again the preceding constructions in the context of profinite groups – unfortunately I lack the necessary foundations, and above all a theory of "hole-making" or "drilling holes" at the level of profinite groups with loops – even some|in a ^{d3} fashion^{i3} conjec-

whether these congruential relations really are relations of an arithmetic nature, specific to outer automorphisms coming from Γ_Q, or on the contrary $\pm$ automatic consequences of a purely "algebraic"[i1] formalism of profinite groups, which would be[i2] modeled on the discrete case. Without prejudging in any way the answer and the degree of plausibility of such a formalism, I could as an experiment try to bring one out, to test|try where it will lead me.

§41 Condition for $\widehat{\Pi}'_{0,3} \xrightarrow{\sim} \widehat{\mathfrak{S}}^+_{0,3}$ to commute with the operations of Γ_Q ; Calculation of outer automorphisms of $\widehat{\Pi}_{0,3}$ and $\widehat{\mathfrak{S}}^+_{0,3}$.

Before embarking on this [d1]path[i3], I would still like to elucidate a question, concerning other possible necessary conditions (in addition to the congruential conditions of §38|39) for a categorical automorphism of $\widehat{\Pi}_{0,3}$ to come

from Γ_Q. For this, let us take up again the composite outer homomorphism

$$\Pi_{0,3} \xrightarrow{\text{epimorphism}} \Pi'_{0,3} \xrightarrow{\sim} \mathfrak{S}^+_{0,3} \simeq \pi_1\big((U^{\mathrm{an}}_{0,3}, \mathfrak{S}_3), P \qquad (1)$$

$$= \Pi_{0,3}/\{\ell_1^2, \ell_\infty^3\}$$

$$\simeq \text{cartographic group}$$

oriented triangulated

defined by

$$\begin{cases} \varphi(\ell_0) = \ell'_0 = \sigma_\infty \rho \\ \varphi(\ell_1) = \ell'_1 = \sigma_\infty \\ \varphi(\ell_\infty) = \ell'_\infty = \rho^{-1} \end{cases} \qquad (2)$$

(with the notation of [C, …] …), which by passing to the completions gives an outer homomorphism

$$\widehat{\varphi} : \widehat{\Pi}_{0,3} \xrightarrow{\text{epimorphism}} \widehat{\mathfrak{S}}^{+}_{0,3} \simeq \pi_1((U_{0,3\overline{Q}_0}, \mathfrak{S}_3), P).$$

(3)

$$\cap$$

$$\widehat{\widehat{\mathcal{T}}}_{0,3} = \mathrm{Aut}_{\mathrm{loc}}(\widehat{\Pi}_{0,3})$$

This homomorphism is defined here [d2]by the[i1] "brutal formulas" (2), without reference to a particular subgroup Γ of $\mathrm{Aut}\,\mathrm{ext}'_{\mathrm{loc}}(\widehat{\Pi}_{0,3})$. If one is given a [d3] subgroup of this kind, commuting with $\mathfrak{S}_3$, it automatically operates on the outer group $\widehat{\mathfrak{S}}^{+}_{0,3}$, since it

The fact that the homomorphism (3) commutes with the action of $\Gamma_Q = \Gamma$ seems to me [d2] a priori a nontrivial condition on Γ – more precisely, on the elements of Γ separately, which one should really manage to make explicit (likewise for the congruential conditions), in terms of the $\pm$ explicit calculations of [C]. This condition is equivalent to the condition that the homomorphism (3) fits into a homomorphism of extensions

[p. 318]

$$(11)\qquad \begin{cases} u(\ell_0) = \mathrm{int}(g_0)(\ell_0^p) \\ u(\ell_1) = \mathrm{int}(\underbrace{\sigma_\infty(g_0)}_{g_1})(\ell_1^p) \\ u(\ell_\infty) = \mathrm{int}(g_0\ell_0^{-\gamma|\sigma}\rho^{-1}(h_0))(\ell_\infty^p) \end{cases},$$

and one must in all rigor, in addition to conditions (9),(10), require that the two elements $u(\ell_0), u(\ell_1)$ given by (11)[i2] form generators of the profinite group $\widehat{\Pi}_{0,3}$. (11 bis)

I am going to calculate the action of u on $\widehat{\mathfrak{S}}^+_{0,3}$, considering this group as generated by the elements

$$(12)\qquad \ell'_1 = \sigma_\infty, \qquad \ell'_\infty = \rho^{-1}$$

so one simply has to calculate $\mathrm{int}(u).\sigma_\infty = u(\sigma_\infty) =^{\mathrm{i3}} u\sigma_\infty u^{-1}$ and $u(\rho) = \mathrm{int}(u).\rho = u\rho u^{-1}$. One has by construction (u commuting with σ_∞)

$$(13)\qquad u{\circ}\sigma_\infty u^{-1} = \sigma_\infty,$$

and on the other hand one verifies that

$$(14)\qquad \begin{cases} \rho^{-1}u\rho = \mathrm{int}(h)u \\ \text{with} \quad h = (\rho^{-1}\sigma_\infty)(g_0)\ell_0^\gamma g_0^{-1} \end{cases}$$

m705

Marginal note. [m705] i.e. $u\rho u^{-1} = \rho\,\mathrm{int}(h)$.
$= \mathrm{int}(\rho(h))\rho$
i.e. $\rho(h) = \sigma_\infty(g_0)\ell_1^\gamma\rho(g_0)^{-1}$

so one finds, in terms of an operation on the group $\widehat{\mathfrak{S}}^+_{0,3}$ generated by $\ell'_1 =^{\mathrm{i5}} \sigma_\infty$ and $\ell'_\infty =^{\mathrm{i6}} \rho^{-1}$ (or ρ)

$$(15)\qquad \begin{cases} u(\sigma_\infty) = \sigma_\infty \\ u(\rho) = g.\rho \end{cases} \quad \text{with} \quad g = \sigma_\infty(g_0)\ell_1^{\gamma|\tau}\rho(g_0)^{-1}$$

[scan 60]

N.B. The relation [d1] $u(\sigma_\infty)^2 = 1$ is trivial, the relation $u(\rho)^3 = 1$ reduces to

$$(16) \qquad g\rho(g)\rho^2(g) = 1$$

which is a consequence of the explicit expression (15) for g, and of formula (10).

Let us note that one [d3] should have[i1], & taking up again

$$\ell'_0 = \sigma_\infty\rho = \varepsilon_0|e_0 \qquad (\text{whence} \quad \ell'^2_0 = \ell_0)$$

$$(17) \qquad u(\ell'_0) = \mathrm{int}(g_0)(\ell'^p_0)$$

[i2] — this relation when|when squared is none other than the first relation (11) ?

$$u(\ell_0) = \mathrm{int}(g_0)(\ell^p_0).$$

[The relation (17) is a consequence of it, if one admits that the centralizer of $L_0 = \ell_0^{\widehat{\mathbb{Z}}}$ in $\widehat{\Pi}_{0,3}$ is reduced to L_0…]

One should also have the relation

$$(18) \qquad u(\rho)\text{conjugate of}\rho^p$$

[d6] to which we are going to return – it is not clear to me that it is a consequence of the conditions considered on u up to now.

Scans 61–70

[scan 61]

[p. 319]

Let us now consider the homomorphism (3)

$$\begin{cases} \widehat{\varphi}: & \widehat{\Pi}_{0,3} \longrightarrow \widehat{\mathfrak{S}}^{+}_{0,3} \\ & \ell_0 \longmapsto \ell'_0 = \sigma_\infty \rho = \varepsilon_0 \\ & \ell_1 \longrightarrow \ell'_1 = \sigma_\infty \\ & \ell_\infty \longmapsto \ell'_\infty = \rho^{-1} \end{cases} \tag{18}$$

and let us write that it commutes, as an outer homomorphism, with u. This therefore means that there exists a

$$\lambda \in \widehat{\mathfrak{S}}^{+}_{0,3} \tag{19}$$

such that we have

$$\widehat{\varphi}(ux) = \lambda\, u\widehat{\varphi}(x)\, \lambda^{-1} \qquad \forall x \in \widehat{\Pi}_{0,3}, \tag{20}$$

and it suffices to express this condition for x equal to one of the two generators ℓ_0, ℓ_1 of $\widehat{\Pi}_{0,3}$

For $x = \ell_0$ relation (20) is written

$$u(\ell'_0) = \mathrm{int}(\lambda^{-1}\widehat{\varphi}(g_0))(\ell'^{p}_0) \tag{21}$$

which, compared with (17), gives

$$\mathrm{int}(g_0^{-1}\lambda^{-1}\widehat{\varphi}(g_0))(\ell'^{p}_0) = \ell'^{p}_0 \quad \text{hence}$$

$$g_0^{-1}\lambda^{-1}\widehat{\varphi}(g_0) = \ell'^{\beta}_0 \qquad (\beta \in \widehat{\mathbb{Z}})$$

or again

$$\boxed{\lambda = \widehat{\varphi}(g_0)\ell'^{-\beta}_0 g_0^{-1}} = \widehat{\varphi}(g_0 h_0^{-1}) = \widehat{\varphi}(\sigma_\infty(g_0)) \tag{22}$$

↘ cf. below (24 bis)

For $x = \ell_1$ relation (20) is written

[scan 63]

[p. 320]

In summary:

Proposition Let us consider an outer automorphism u of the group with loops $\widehat{\Pi}_{0,3}$, realized by $g_0 \in \widehat{\Pi}_{0,3}$ modulo L_0,[i1] and $p \in \widehat{\mathbb{Z}}^*$, (and $\gamma \in \widehat{\mathbb{Z}}^*$ uniquely determined by terms|in terms of g_0 and p) by formulas (11), by means of an actual automorphism (still denoted u)[i2] which commutes with σ_∞ — the data g_0, p (and γ) being therefore[i3] required to satisfy conditions (9) and (10) above, plus the generation condition (11 bis). (We extend u to an automorphism of $\widehat{\mathfrak{S}}^{+}_{0,3}$ by int(u), cf. (15))[i4] For the outer homomorphism $\widehat{\varphi} : \widehat{\Pi}_{0,3} \longrightarrow \widehat{\mathfrak{S}}^{+}_{0,3}$ defined by (18) to commute with the outer action of u, it is necessary and sufficient that we can find a $\beta \in \widehat{\mathbb{Z}}$, such that we have (24), or what amounts to the same, (27),

better: 24 bis

This condition (for β fixed)[i5] is also equivalent to formula (20) for $x = \ell_\infty$ (λ being always given by (22)), [d1] i.e. to the formula

$$u(\ell'_\infty) = \mathrm{int}(\lambda^{-1} \widehat{\varphi}(g_\infty))(\ell'^{\,p}_\infty), \qquad \text{where} \tag{28}$$

$$g_\infty = g_0 \ell_0^{-\gamma} \rho^{-1}(h_0) \qquad (\text{and } \lambda \text{ given by (22)}). \tag{29}$$

[scan 64]

formula which thus makes precise the presumptive formula (18). It is also written, more explicitly

$$\rho^{-1}g^{-1} = \mathrm{int}(g_0\varepsilon_0^{\beta}\widehat{\varphi}(\ell_0^{\gamma}\rho^{-1}(h_0)))(\rho^{-p})$$

$$g_0\varepsilon_0^{\beta+\gamma}\widehat{\varphi}(\rho^{-1}(h_0))$$

i1 i.e. (taking inverses, and making g explicit)

$$(30) \qquad \boxed{h_0^{-1}\ell_1^{\gamma}\rho = \mathrm{int}(\varepsilon_0^{\alpha}\widehat{\varphi}(\rho^{-1}(h_0)))(\rho^{p})}$$

m715

Marginal note. m715 N.B. We put $\alpha = \beta + \gamma$. The existence of $\beta \in \widehat{\mathbb{Z}}$ satisfying (24), is equivalent to that of $\alpha \in \widehat{\mathbb{Z}}$ satisfying (30).

The equivalence of (24) and (30) may seem a little strange, owing to the fact for example i4 that in (24) the exponent p does not enter explicitly, but only h_0, whereas formula (30) brings in the value of $p \in \widehat{\mathbb{Z}}^*$ modulo 3 (which gives $\rho^p = \rho$ or $\rho^p = \rho^{-1}$). But in any event, whether it be in the form (24) where|or in the form (30), it does seem that the condition in question is highly non-tautological!

To do things properly, it would be necessary to first make explicit the congruential conditions of § 39 in terms of g_0, p.

[scan 65]

[p. 321]

I would like to compare the outer automorphisms of $\widehat{\Pi}_{0,3}$, and those of $\widehat{\mathfrak{S}}^{+}_{0,3}$, taking account of the exact sequence

$$(31)\qquad 1 \longrightarrow \widehat{\Pi}_{0,3} \longrightarrow \widehat{\mathfrak{S}}^{+}_{0,3} \longrightarrow \mathfrak{S}_3 \longrightarrow 1$$

$$\wr$$

$$\widehat{\Pi'}_{0,3}$$

d1 Let us note[i3] that every outer automorphism u[i4] of $\widehat{\mathfrak{S}}^{+}_{0,3}$ which leaves invariant the normal subgroup $\widehat{\Pi}_{0,3}$, and induces on the quotient $\mathfrak{S}_3$ a trivial outer automorphism, can be written as obtained from an automorphism u_0[i5] of $\widehat{\mathfrak{S}}^{+}_{0,3}$, stabilizing $\widehat{\Pi}_{0,3}$, and inducing the identity on the quotient $\mathfrak{S}_3$ — and u_0 is then determined modulo composition with an element $\mathrm{int}(g)$, where $g \in \widehat{\mathfrak{S}}^{+}_{0,3}$ is such that its image in $\mathfrak{S}_3$ is central, i.e. $= 1$, i.e. $g \in \widehat{\Pi}_{0,3}$. Thus

$$(32)\qquad \begin{array}{c}\text{group of outer automorphisms}\\ \text{of } \widehat{\mathfrak{S}}^{+}_{0,3} \text{ which}\\ \text{induce on } \mathfrak{S}_3 \text{ a}\\ \text{trivial outer automorphism (hence leave invariant}\\ \widehat{\Pi}_{0,3})\end{array} \simeq \begin{array}{c}\text{group of}\\ \text{automorphisms of}\\ \widehat{\mathfrak{S}}^{+}_{0,3} \text{ which}\\ \text{induce}\\ \text{the identity on}\\ \text{its quotient } \mathfrak{S}_3,\\ \text{modulo the sub-}\\ \text{group of}\\ \text{inner automorphisms}\\ \text{by } g \in \widehat{\Pi}_{0,3}\end{array}$$

[scan 66]

Is such[i1] an automorphism u_0 determined by its restriction to $\widehat{\Pi}_{0,3}$? In other words, an automorphism of $\widehat{\mathfrak{S}}^+_{0,3}$ [d1] ($\simeq \mathrm{Sl}(2|1,\mathbb{Z})'^{\wedge}$) which induces the identity on $\widehat{\Pi}_{0,3}$ and on $\mathfrak{S}_3$, is it trivial? It suffices to prove that its restriction to the inverse image $\widehat{\Pi}_{0,\infty|0,3}\cdot\{1,\sigma_\infty\}$[i2] of $\{1,\dot\sigma_\infty\}\subset\mathfrak{S}_3$ is trivial|trivial (by symmetry this will also be the case on replacing $\dot\sigma_\infty$ by $\dot\sigma_0,\dot\sigma_1$, now these three subgroups generate $\widehat{\mathfrak{S}}^+_{0,3}$. We will have $f(\sigma_\infty)=\sigma_\infty g$, with $g\in\widehat{\Pi}_{0,3}$ [and we must have $\sigma_\infty g\sigma_\infty g=1$ i.e.

$$g\cdot\sigma_\infty(g)=1$$

] moreover [d2] we will have to have that[i3]

$$\mathrm{int}(\sigma_\infty g)|\widehat{\Pi}_{0,3}=\ \mathrm{int}(\sigma_\infty)|\widehat{\Pi}_{0,3}$$

whence [d4]

$$\mathrm{int}(g)|\widehat{\Pi}_{0,3}=\mathrm{id}\quad\text{i.e.}\quad g\in\mathrm{Centre}(\widehat{\Pi}_{0,3})\quad\text{i.e.}\quad g=1,$$

OK.

But under what condition does an automorphism of $\widehat{\Pi}_{0,3}$ [d5] extend to an automorphism of $\widehat{\mathfrak{S}}^+_{0,3}$ which [d6]induces[i4] the identity on $\mathfrak{S}_3$? We see at once that it is necessary for this that the outer automorphism of $\widehat{\Pi}_{0,3}$ which it induces commute with the action of $\mathfrak{S}_3$.

[p. 322|332]

This is sufficient, for let $\Gamma \subset \operatorname{Aut}\operatorname{ext}(\widehat{\Pi}_{0,3})$ be the group of outer automorphisms of $\widehat{\Pi}_{0,3}$ which have this property (we are not concerned for the moment with the loop structure of $\widehat{\Pi}_{0,3}$), we have $\Gamma \cap \mathfrak{S}_3 = (1)$ (identifying $\mathfrak{S}_3$ with a subgroup of $\operatorname{Aut}\operatorname{ext}\widehat{\Pi}_{0,3}$) for [d1] the center of $\mathfrak{S}_3$ is trivial, hence

this is evident|evidently

$$\mathfrak{S}_3 \times \Gamma \hookrightarrow \operatorname{Autext}(\widehat{\Pi}_{0,3}),$$

and we thus have an extension structure

$$1 \longrightarrow \widehat{\Pi}_{0,3} \longrightarrow \mathcal{E} \longrightarrow \mathfrak{S}_3 \times \Gamma \longrightarrow 1 \tag{33}$$

(for the center of $\widehat{\Pi}_{0,3}$ is trivial), or again an extension structure

$$1 \longrightarrow \widehat{\mathfrak{S}}^{+}_{0,3} \longrightarrow \mathcal{E} \longrightarrow \Gamma \longrightarrow 1 \tag{34}$$

which defines an outer action of Γ on $\widehat{\mathfrak{S}}^{+}_{0,3}$ — which is the outer action sought. Thus

Proposition the group of outer automorphisms of $\widehat{\Pi}_{0,3}$ which commute with $\mathfrak{S}_3$ is canonically isomorphic to the group of outer automorphisms of $\widehat{\mathfrak{S}}^{+}_{0,3}$ which induce on $\mathfrak{S}_3$ the trivial outer automorphism.

But every automorphism of $\mathfrak{S}_3$ is inner!

[p. 323]

writing that u is an endomorphism (for we recall that $\widehat{\mathfrak{S}}^+_{0,3}$ is defined by the generators σ_∞, ρ with the relations

$$\sigma_\infty^2 = \rho^3 = 1 \tag{37}$$

we find the condition

$$(g\rho)^3 = 1 \qquad \text{i.e.} \qquad g\,\rho(g)\,\rho^2(g) = 1. \tag{38}$$

m720

Marginal note. m720 moreover it is necessary in order that σ_∞ and $g\rho$ generate $\widehat{\Pi}_{0,3}$, with only relations $\sigma_\infty^2 = (g\rho)^3 = 1$.

Corollary. Let $u \in \mathcal{E}^!$ be an automorphism of $\widehat{\mathfrak{S}}^+_{0,3}$ which induces the identity on $\mathfrak{S}_3$. Equivalent conditions:

a) $\exists\ p \in \widehat{\mathbb{Z}}^*$ such that $u(\underline{\ell'_0}_{\varepsilon_0})$ conjugate in $\widehat{\mathfrak{S}}^+_{0,3}$ to $\ell_0'^p$ (this p is then unique, and we can conjugate by an element of $\widehat{\Pi}_{0,3}$ i1).

b) $\exists\ p \in \widehat{\mathbb{Z}}^*$ such that $u(\ell_0)$ is conjugate in $\widehat{\Pi}_{0,3}$ to ℓ_0^p (this p is then unique).

c) $u_0 \overset{\text{dfn}}{=} u \mid \widehat{\Pi}_{0,3}$ respects the loop structure of $\widehat{\Pi}_{0,3}$.

Moreover, the p in a) and b) is the same.

Proof. If $u(\ell'_0) = \mathrm{int}(g_0)(\ell_0'^p)$, with $g_0 \in \widehat{\mathfrak{S}}^+_{0,3}$, squaring we will have $u(\ell_0) = \mathrm{int}(g_0)(\ell_0^p)$, this shows that the image $\dot{g}_0$ of g_0 in $\mathfrak{S}_3$ leaves invariant 0 i.e. is d1 1 or $\dot{\sigma}_0$, d2 if it is 1 we do have b), otherwise we put|† d3 $g_0 = h\sigma_0$ ($h \in \widehat{\Pi}_{0,3}$) i2 d4

$$u(\ell_0) = \mathrm{int}(h)\,\frac{\sigma_0(\ell_0^p)}{(\sigma_0(\ell_0))^p}$$

now we know that $\sigma_0(\ell_0) = \mathrm{int}(a)\ell_0$ (with $a \in \widehat{\Pi}_{0,3}$) i3, whence $\sigma_0(\ell_0)^p = \mathrm{int}(a)\ell_0^p$ i4, thus $u(\ell_0) = \mathrm{int}(ha)(\ell_0^p)$, whence b) with the same p.

Text: insertion integrated Reason: Explicit authorial insertion: integrated at the position recorded by the transcription, without changing its reading.

[scan 70]

Since we know the uniqueness of p in b), in a) too. If we have

$$u_0(\ell_0) = \mathrm{int}(g_0)(\ell_0^p) \qquad (g_0 \in \widehat{\Pi}_{0,3}) \tag{39}$$

we deduce from this, writing

$$\rho u_0 \rho^{-1} = \mathrm{int}(g^{-1}) u_0 \qquad (a|g \in \widehat{\Pi}_{0,3})$$

$$u_0(\ell_1) = \mathrm{int}(a|g)\,\rho\,u_0\,\underbrace{\underbrace{\rho^{-1}(\ell_1)}_{\ell_0}}_{\mathrm{int}(g_0)(\ell_0^p)}\Big\}_{\mathrm{int}(\rho(g_0))(\ell_1^p)} = \mathrm{int}(g\rho(g_0))(\ell_1^p)$$

i.e.

$$u_0(\ell_1) = \mathrm{int}(g_1)(\ell_1^p) \qquad \text{with} \quad g_1 = g\rho(g_0) \tag{40}$$

and likewise

$$u_0|u(\ell_\infty) = \mathrm{int}(g_\infty)(\ell_\infty^p) \qquad \text{with} \quad \begin{matrix} g_\infty = g\rho(g_1) \\ = g\rho(g)\rho^2(g_0) \end{matrix} \tag{41}$$

thus b) ⇒ c). Finally let us prove c) ⇒ a).

We have by hypothesis

$$\begin{matrix} u_0(\ell_0) & = & \mathrm{int}(g)\ell_0^p \\ \text{"} & & \text{"} \\ u(\varepsilon_0)^2 & & \mathrm{int}(g)(\ell|\varepsilon_0^{2p|p})^2 = (\mathrm{int}\, g(\ell_0^p|\varepsilon_0^p))^2 \end{matrix}$$

I say that we then have

$$u(\varepsilon_0) = \mathrm{int}(g)(\varepsilon_0^p).$$

It suffices to [d3]recall[i1] that [d4]the only[i2] element of $\widehat{\mathfrak{S}}_{0,3}^+$ with square equal to ℓ_0 is ε_0… OK check

Scans 71–80

[scan 71]

[p. 324]
d1

Henceforth we restrict ourselves to the automorphisms (actual or[i1] outer) of $\widehat{\Pi}_{0,3}$ which respect the loop structure, and commute with $\mathfrak{S}_3$ (as outer actions) — which correspond to the automorphisms (actual or outer)[i2] of $\widehat{\mathfrak{S}}^{+}_{0,3}$ which induce the identity on $\mathfrak{S}_3$, and satisfy a) above.
d2

The outer automorphisms of this nature correspond therefore to the actual automorphisms u of $\widehat{\Pi}_{0,3}$[i3] which commute with σ_∞, i.e. u of $\widehat{\mathfrak{S}}^{+}_{0,3}$[i4] which fix σ_∞, and are determined by a $g \in \widehat{\Pi}_{0,3}$ satisfying (38), and such that in addition there exist $p \in \widehat{\mathbb{Z}}^*$ and[i5] $g_0 \in \widehat{\Pi}_{0,3}$ satisfying

$$(39) \qquad u(\ell_0') = \mathrm{int}(g_0)(\ell_0'^{\,p}) \qquad \text{i.e.} \qquad u(\ell_0) = \mathrm{int}(g_0)(\ell_0^p)$$

(where|i.e. g_0 is determined modulo $L_0 = \ell_0^{\widehat{\mathbb{Z}}}$ ...). Calculations made elsewhere show then[i6] that we must have

$$(40) \qquad g = \sigma_\infty(g_0)\, \ell_1^{\gamma}\, \rho(g_0)^{-1}$$

m722

Marginal note. [m722] with $\gamma \in \widehat{\mathbb{Z}}$ well determined (independent of the choice of g_0)

i.e.

$$(41) \qquad \sigma_\infty(g_0)^{-1}\, \underbrace{g\rho(g_0)}_{g_1} \in L_1 = \mathcal{N}|N|\mathrm{Norm}_{\widehat{\Pi}_{0,3}}(L_1)$$

[scan 72]

Indeed, we have by hypothesis on g_0 (cf. (39))

$$u(L_0) = \mathrm{int}(g_0)(L_0) \tag{42}$$

†[d1]|hence

$$\begin{array}{l} u\sigma_\infty(L_0) = u(L_1) \overset{40}{=} \mathrm{int}(g_1)(L_1) \\ \| \quad (\text{since } u\sigma_\infty = \sigma_\infty u) \\ \sigma_\infty u(L_0) \underset{(42)}{=} \sigma_\infty(\mathrm{int}(g_0)(L_0)) = \mathrm{int}(\sigma_\infty(g_0))(\sigma_\infty(L_0)) = \mathrm{int}(\sigma_\infty(g_0))(L_1) \end{array}$$

hence

$$\mathrm{int}(\sigma_\infty(g_0)^{-1} g_1)(L_1) \subset L_1$$

therefore

$$\sigma_\infty(g_0)^{-1} \underbrace{g_1}_{g\rho(g_0)} \in \mathcal{N}_{\widehat{\Pi}_{0,3}}(L_1) = L_1$$

hence

$$\sigma_\infty(g_0)^{-1} g_1 | g\rho(g_0) = \ell_1^\gamma \qquad (\gamma \in \widehat{\mathbb{Z}})$$

hence (40). We will note, to return to it, that the element g defined in terms of a g_0 and of γ[i1] indeed depends only on g_0 modulo L_0. [d2] ✓

m724

Marginal note. [m724]

Thus; the datum of u_0 [d3] a loop outer automorphism[i2] of $\widehat{\Pi}_{0,3}$ commuting with $\mathfrak{S}_3$, or again an|u outer automorphism of $\widehat{\mathfrak{S}}^+_{0,3}$ inducing the identity in $\mathfrak{S}_3$ and [d4] leaving invariant[i3] the conjugacy class of the loop subgroup $L'_0 = \varepsilon_0^{\widehat{\mathbb{Z}}} = {\ell'_0}^{\widehat{\mathbb{Z}}} = \widehat{\varphi}(L_0)$, or again that of a loop automorphism u_0 of $\widehat{\Pi}_{0,3}$ commuting with σ_∞, and in the outer automorphism quotien[t] with ρ, or again of an automorphism u of $\widehat{\mathfrak{S}}^+_{0,3}$ which fixes σ_∞, and which fixes ρ modulo $\widehat{\Pi}_{0,3}$ — is equivalent to the datum of $g_0 \in \widehat{\Pi}_{0,3}$ modulo L_0, and of $\gamma \in \widehat{\mathbb{Z}}$, satisfying the relation

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

140-3-s073-D019 *deletion. Manuscript:* (44) $\quad u(\ell_0') = u(\varepsilon_0) = \mathrm{int}(g_0)(\ell'$
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 74]

$$(44) \qquad u(\ell_0') = \mathrm{int}(g_0)(\ell_0'^p) \qquad \text{with} \quad \underline{\underline{p = 2\gamma + 1}}$$
$$\Vert_{\varepsilon_0} \qquad\qquad \Vert_{\varepsilon_0}$$

hence (39), d1 on raising to the square:

$$u(\ell_0) = \mathrm{int}(g_0)(\ell_0^p).$$

d2 N.B. We will note that if $p \in \widehat{\mathbb{Z}}^*$, then $p - 1 \in 2\widehat{\mathbb{Z}}$ i.e. $\frac{p-1}{2} \in \widehat{\mathbb{Z}}$, since it suffices to check the analogous relation for a $p \in \mathbb{Z}_\ell^*$, for|that $p - 1 \in 2\mathbb{Z}_\ell$, now if $\ell \neq 2$ we have $2\mathbb{Z}_\ell = \mathbb{Z}_\ell$ OK, there remains the case $\ell = 2$ $p \in \mathbb{Z}_2^*$ so the image of p in $\mathbb{Z}/4\mathbb{Z}$ is 1 or 3 so $p - 1 \equiv 0$ or $2 \bmod 4$ d3 so $\frac{p-1}{2} \in \mathbb{Z}_2$, OK.
d4

It therefore remains to express condition (38), and we write it d5

$$\underbrace{\sigma_\infty(g_0)\ell_1^\gamma \rho(g_0^{-1})}\ \underbrace{\rho\sigma_\infty(g_0)\ell_\infty^\gamma \rho^2(g_0^{-1})}\ \rho^2\sigma_\infty(g_0)\ell_0^\gamma g_0^{-1} = 1$$

i.e., on applying $\mathrm{int}(g_0^{-1})$ and [d6]setting again[i1] (cf. (8))

$$(45)\qquad g_0^{-1}\sigma_\infty(g_0)=h_0^{-1}\qquad \text{i.e.}\quad h_0=\sigma_\infty(g_0)^{-1}g_0=[\sigma_\infty,g_0^{-1}]$$
$$h_0^{-1}\ell_1^\gamma\,\underbrace{\rho(h_0^{-1})\ell_\infty^\gamma}\,\rho^2(h_0^{-1})\ell_0^\gamma=1$$

or again, on applying $\mathrm{int}(\ell_0^\gamma)$

$$(46)\qquad \boxed{\underbrace{(\ell_0^\gamma h_0^{-1})}\cdot\rho(\ell_0^\gamma h_0^{-1})\cdot\rho^2(\ell_0^\gamma h_0^{-1})=1}\qquad \left(\text{where }\gamma=\frac{p-1}{2}\right)$$

which is none other than (10). As for the condition (9)|(7), we see that it is superfluous, i.e.,[i2] automatically satisfied.

[scan 75]

[p. 326]

Let us sum up:

Theorem An outer automorphism with loops|with loops[i1] of $\widehat{\Pi}_{0,3}$ commuting with $\mathfrak{S}_3$, lifts uniquely as an automorphism of the group with loops|with loops $\widehat{\Pi}_{0,3}$, commuting with σ_∞ (and commuting with ρ modulo inner|inner automorphisms), or again as the restriction of an automorphism u of $\widehat{\mathfrak{S}}^+_{0,3}$ which fixes σ_∞, leaves invariant ρ modulo $\widehat{\Pi}_{0,3}$ (i.e. fixes[i2] $\dot\rho$ in $\mathfrak{S}_3$), and which leaves invariant the conjugacy class of the closed[i3] subgroup $L_0'=\widehat{\varphi}(L_0)$[i4] [d1] generated by $\ell_0'=\varepsilon_0=\sigma_\infty\rho$. (or again of the closed[i5] subgroup $L_0=(L_0')^2$ generated by ℓ_0). The datum of such a u is equivalent to that of its multiplier $p\in\widehat{\mathbb{Z}}^*$, and of a $g_0\in\widehat{\Pi}_{0,3}/L_0$ satisfying the following conditions

a) Setting

$$(47)\qquad \begin{cases} h_0=\sigma_\infty(g_0)^{-1}g_0=[\sigma_\infty,g_0^{-1}] & (\in\widehat{\Pi}_{0,3})\\ \gamma=\dfrac{p-1}{2}\in\widehat{\mathbb{Z}}\end{cases}$$

we have relation (46) above (invariant under replacement of g_0 by $g_0\ell_0^\lambda$, $\lambda \in \widehat{\mathbb{Z}}$)

$$(48) \qquad (\underbrace{\ell_0^\gamma h_0^{-1}}_{\xi_0})\rho(\ell_0^\gamma h_0^{-1})\rho^2(\ell_0^\gamma h_0^{-1}) = 1$$

m729

Marginal note. m729 i.e. $\xi_0\rho(\xi_0)\rho^2(\xi_0) = 1$ with $\xi_0 = \ell_0^\gamma h_0^{-1}$

b) σ_∞ and $g\rho$ generate topologically $\widehat{\mathfrak{S}}^+_{0,3}$, where g is given in terms of g_0 by 40

$$[(40)] \qquad g = \sigma_\infty(g_0)\ell_1^\gamma\rho(g_0)^{-1} = \sigma_\infty(g_0\ell_0^\gamma)\rho(g_0^{-1})$$

m730

Marginal note. m730 $= g_0(h_0^{-1}\ell_1^\gamma)\rho(g_0)^{-1}$
$= (g_0\ell_0^{-\gamma})(\ell_0^\gamma h_0^{-1})(\rho(g_0\ell_0^{-\gamma}))^{-1}$

d2 (N.B. relation (46) is equivalent to: $(g\rho)^3 = 1$ i.e. to[i6]

$$(38) \qquad g\rho(g)\rho^2(g) = 1,$$

expressed directly in terms of g_0, $\gamma = \frac{p-1}{2}$), with the generating relations $\sigma_\infty^2 = (g\rho)^3 = 1$. The (36)
automorphism u is given in terms of g_0 and p by

(where necessarily $\alpha = \beta + \gamma$).
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 77]

[p. 327]

Scholium In the theorem, the $g \in \widehat{\Pi}_{0,3}$ i1 (which enters directly in writing u) is expressed by means of the $g_0 \in \widehat{\Pi}_{0,3}$ i2 and $\gamma = \frac{p-1}{2}$, d1 (g_0 defined modulo L_0) — condition (46) being in fact a condition which is expressed directly in terms of g_0, or better still, in terms of

$$(50)\qquad \xi_{\dagger|0} = \ell_0^\gamma h_0^{-1} \in \widehat{\Pi}_{0,3} \quad (\text{whence } h_0 = \xi_{\dagger|0}^{-1}\ell_0^\gamma)$$

as

$$(51)\qquad \xi\rho(\xi)\rho^2(\xi) = 1,$$

which is equivalent to

$$(52)\qquad (\xi\rho)^3 = 1.$$

The solutions of equation (51), or what amounts to the same thing of (52), correspond to the splittings of the|the sub-i3extension of $\widehat{\mathfrak{S}}^+_{0,3}$ i4 of $\mathbb{Z}/3\mathbb{Z}$ by $\widehat{\Pi}_{0,3}$, generated by $\rho \in \mathfrak{S}_3$, d4 i.e. to

the elements of order 3 of $\widehat{\mathfrak{S}}^{+}_{0,3}$ above $\dot{\rho}$. On the set of these splittings resp. of these elements $\xi\rho$, $\widehat{\Pi}_{0,3}$ operates by inner automorphisms:

$$\text{(53)} \qquad \mathrm{int}(\lambda)(\xi\rho) = \lambda\xi\rho\lambda^{-1} = \lambda\xi\rho\lambda^{-1}\rho^{-1}\rho = (\lambda\xi\rho(\lambda)^{-1})\rho$$

i.e. it operates on the set of solutions of (51), by

$$\text{(54)} \qquad {}^{\lambda}\xi = \lambda\xi\rho(\lambda)^{-1}$$

N.B. $\lambda \mapsto {}^{\lambda}\xi$ is injective

[scan 78]

Let us admit (leaving it to be checked later) that there are exactly two conjugacy classes: that of $\xi_0 = 1$, corresponding to the tautological splitting, ^{d1}in^{i1} such a way that for such ξ we will have

$$\text{(55)} \qquad \xi = \lambda\rho(\lambda)^{-1} \qquad (\lambda \in \widehat{\Pi}_{0,3}),$$

and on the other hand the conjugacy class of the lift^{t} of order 3 $\sigma_\infty\rho^{-1}\sigma_\infty^{-1} = \sigma_\infty\rho^{-1}\sigma_\infty$ of $\dot{\rho}$, corresponding to

$$\sigma_\infty\rho^{-1}\sigma_\infty = \xi_0\rho, \quad \text{with}$$

$$\begin{cases} \xi_0 = \sigma_\infty\rho^{-1}\sigma_\infty\rho^{-1} = \sigma_\infty \underbrace{(\rho^{-1}\sigma_\infty)}_{\varepsilon_0^{-1}}(\rho^{-1}\sigma_\infty)\sigma_\infty \\ \quad = \sigma_\infty\varepsilon_0^{-2}\sigma_\infty = \sigma_\infty(\ell_0^{-1}) = \ell_1^{-1} \end{cases}$$

(and we do indeed have

$$\ell_1^{-1}\rho(\ell_1^{-1})\rho^2(\ell_1^{-1}) = \ell_1^{-1}\ell_\infty^{-1}\ell_0^{-1} = (\ell_0\ell_\infty\ell_1)^{-1} = 1$$

), This orbit corresponds to solutions of the form d3

$$(56) \qquad \xi = \lambda \ell_0^{-1} \rho(\lambda)^{-1} \qquad (\lambda \in \widehat{\Pi}_{0,3})$$

[we will note that ℓ_0^{-1} and ℓ_1^{-1} are in the same orbit

$$\ell_1^{-1} = \ell_0(\ell_0^{-1})\rho(\ell_0)^{-1}$$

]

[scan 79]

[p. 328]

It remains then to solve the equation in g_0 (47)

$$(58) \qquad \sigma_\infty(g_0)^{-1} g_0 = \underbrace{\rho(\lambda)\lambda^{-1}\ell_0^{\gamma}}_{h_0}$$

For $\forall|$a fixed h_0, there is at most a single g_0 which satisfies this condition, and such a g_0 exists iff d1, which is written

using that $\widehat{\Pi}_{0,3}^{\sigma_\infty} = \{1\}$

$$(59) \qquad \sigma_\infty(h_0)\cdot h_0 = 1 \qquad \text{or again } h_0\sigma_\infty(h_0) = 1$$

d2

which is also written, taking up again the expression $h_0 = \xi^{-1}\ell_0^\gamma$

$$\sigma_\infty(\xi)^{-1}\ell_1^\gamma\xi^{-1}\ell_0^\gamma = 1 \qquad \text{i.e.}$$

$$(60) \qquad \sigma_\infty(\xi) = \ell_1^\gamma\cdot\xi^{-1}\cdot\ell_0^\gamma$$

In summary

Corollary The u which do not change the $\widehat{\Pi}_{0,3}$-[i2]conjugacy class of ρ [d4] correspond 1-1 to the systems $(\lambda, p) \in L_0\backslash\widehat{\Pi}_{0,3}\times\widehat{\mathbb{Z}}^*$, such that — setting $\xi = \lambda\rho(\lambda)^{-1}$, $\gamma = \frac{p-1}{2}$,[i3] we have relation (60). We will note that for λ hence ξ fixed, there exists at most one $\gamma\in\widehat{\mathbb{Z}}$ such that relation (60) holds, hence p is determined by λ, subject to the additional condition that the element[i4] $2\gamma+1$ of $\widehat{\mathbb{Z}}$ be in $\widehat{\mathbb{Z}}^*$ (i.e. $\exists\gamma'\in\widehat{\mathbb{Z}}^*$ with $2\gamma\gamma'+\gamma+\gamma' = 0$)

[scan 80]

N.B. If λ is replaced by $\lambda' = \ell_0^\alpha\lambda$, $\xi = \lambda\rho(\lambda)^{-1}$ is replaced by $\xi' = \ell_0^\alpha\cdot\xi\rho(\ell_0)^{-\alpha}$, and $h_0 = \xi^{-1}\ell_0^\gamma$ is replaced by $h_0' = \rho(\ell_0)^\alpha h_0\ell_0^{-\alpha}$, finally g_0 is replaced by $g_0' = g_0\ell_0^{-\alpha}$, OK. ! (Equation (60) for ξ or for ξ' is equivalent)

Finally, whether u changes or does not change the $\widehat{\Pi}_{0,3}$-conjugacy class of ρ, the clearest approach for determining the u in question seems to me to be this:

1°) We choose a $\xi\in\widehat{\Pi}_{0,3}$ [i1] satisfying the equation

$$(A) \qquad \xi\rho(\xi)\rho^2(\xi) = 1$$

(we will take it either in the form (55), or in the form (56)[d1] :

$$(B) \qquad \xi = \lambda\rho(\lambda)^{-1} \quad \text{or} \quad \xi = \lambda\ell_0^{-1}\rho(\lambda)^{-1} \quad , \quad \text{with } \lambda\in\widehat{\Pi}_{0,3}$$

)

2°) We choose $\gamma \in \widehat{\mathbb{Z}}$ such that

$$(C) \qquad \sigma_\infty(\xi) = \ell_1^\gamma \xi^{-1} \ell_0^\gamma$$

m737

Marginal note. m737 here, ξ is thus given in terms of λ by by|by (B)

which determines γ uniquely. We will in 1°)|2°) have to restrict ourselves to the ξ (i.e. to the λ)[i2] for which such a γ exists, and such moreover that $p = 2\gamma + 1$ be $\in \widehat{\mathbb{Z}}^*$.

Scans 81–90

[scan 81]

[p. 329]

3°) We then construct

$$h_0 = \xi^{-1} \ell_0^\gamma \in \widehat{\Pi}_{0,3}$$

The relation in 2°) ensures that $h_0 \sigma_\infty(h_0) = 1$ i.e. that h_0 can be put in the form

$$h_0 = \sigma_\infty(g_0)^{-1} g_0$$

with $g_0 \in \widehat{\Pi}_{0,3}$.

m738

Marginal note. m738 N.B. We should make sure on the other hand that knowledge of g_0 does not determine γ i.e. p i.e. that [d1] the γ such that $\xi = \ell_0^\gamma h_0^{-1}$ satisfies (A) is not [d2] unique. To be clarified!

4°) We can now put

$$g = \sigma_\infty(g_0) \ell_1^\gamma \rho(g_0)^{-1} = (g_0 \ell_0^{-\gamma}) \xi \rho(g_0 \ell_0^{-\gamma})^{-1}$$

and we [d3] have what is needed to define u, via

$$\begin{cases} u(\sigma_\infty) = \sigma_\infty \\ u(\rho) = g\rho \end{cases}$$

Here, the only delicate equation, [d4] which the existence (not the uniqueness, in the good case) of a solution, is problematic, is equation C (in $\gamma \in \widehat{\mathbb{Z}}$) — plus the further condition that $2\gamma + 1 \in \widehat{\mathbb{Z}}^*$. This is therefore a [d5]condition[i1] on $\lambda \in \widehat{\Pi}_{0,3}$ — or rather two types of condition, according as ξ is defined in terms of λ by one or the other formula (B).

I expect that we are in one or

the other case of formulas (B), according as p mod 3 is congruent to 1, or to -1 (N.B. it must not be congruent to 0, since p mod $3 \in (\mathbb{Z}/3\mathbb{Z})^*$) i.e. according as $2\gamma \equiv 0$ or -2 (3) i.e. $\gamma \equiv 0$ or -1 (3) (N.B. γ must not be $\equiv 1$ (3), otherwise $2\gamma + 1 = p$ would be congruent to 0 mod (3)). This is in any case what will be the case if $u \in \Gamma_{\mathbb{Q}_0}$.

To test this, let us reduce the [d1]group[i1] $\widehat{\mathfrak{S}}^+_{0,3}$ modulo the[d2,i2] equation|equations $\ell_0^3 = 1$ i.e. $(\sigma_\infty \rho)^6 = 1$

so that $\widehat{\mathfrak{S}}^+_{0,3}$ is replaced by an extension of $\mathfrak{S}_3$ by the group defined by the generators $\ell_0, \ell_1, \ell_\infty$ satisfying

$$\ell_0{}^3 = \ell_1^3 = \ell_\infty^3 = (\ell_\infty \ell_1 \ell_0) = 1$$

— or better, let us use

$$\widehat{\mathfrak{S}}^+_{0,3} \simeq \mathrm{Sl}(2, \mathbb{Z})'^\wedge$$

and reduce directly in

$$\mathrm{Sl}(2, \mathbb{Z}/6\mathbb{Z})' \simeq \mathrm{Sl}(2, \mathbb{Z}/2\mathbb{Z}) \times \mathrm{Sl}(2, \mathbb{Z}/3\mathbb{Z})'.$$

[scan 83]

[p. 330]

But to do the calculations, we must be able to identify σ_∞ and[i1] ρ as elements of $\mathrm{Sl}(2, \widehat{\mathbb{Z}}|\mathbb{Z})$ — an explicitation which we shall carry out presently.

Returning to (24 bis), and putting $h_0|h_\infty = \xi^{-1}\ell_0^\gamma$ into it, we get

$$g_0 = \widehat{\varphi}(\xi)\varepsilon_0^{\gamma-\beta} \tag{61}$$

We thus think that u corresponds to $(\xi, g_0, \gamma, \beta)$, with $\xi, g_0 \in \widehat{\Pi}_{0,3}$ and $\gamma, \beta \in \widehat{\mathbb{Z}}$ satisfying [illeg. 1]

$$\begin{cases} \xi\rho(\xi)\rho^2(\xi) = 1 \\ \xi \underbrace{\sigma_\infty(g_0)^{-1} g_0}_{h} = \ell_0^\gamma \\ g_0 = \widehat{\varphi}(\xi)\varepsilon_0^{\gamma-\beta} \\ 2\gamma + 1 \in \widehat{\mathbb{Z}}^* \end{cases} \tag{62}$$

from which we can eliminate g_0, and we find equations in (ξ, r, s) $(r = \gamma - \beta,\ s = \gamma + \beta)$

$$\begin{cases} \xi\rho(\xi)\rho^2(\xi) = 1 \\ \sigma_\infty\big(\widehat{\varphi}(\xi)\big)^{-1}\widehat{\varphi}(\xi) = \varepsilon_1^r \xi^{-1} \varepsilon_0^s \\ \underbrace{r + s + 1}_{p} \in \widehat{\mathbb{Z}}^* \end{cases} \tag{63}$$

m742

Marginal note. [m742] (thus $\xi = \lambda\rho(\lambda)^{-1}$ or $\xi = \lambda\ell_0^{-1}\rho(\lambda)^{-1}$

Here, λ is determined modulo transformation into $\lambda' = \ell_0^\alpha\lambda$ thus ξ becomes $\xi' = \ell_0^\alpha\xi\ell_1^{-\alpha}$ 82

42 Recapitulation on the group

$$(\mathfrak{S}_{0,3}) \simeq (\Pi_1(U_{0,3}^{\mathrm{an}}, \mathfrak{S}_3; -\bar{j})) \simeq (\widetilde{\Pi}'_{0,3} \simeq \Pi_1((\mathbb{P}^{1\mathrm{an}}, 0\{0\} + 2\{1\} + 3\{\infty\}), \{1, \tau\}; -\bar{j}))$$

$$\simeq (\mathrm{Gl}(2,\mathbb{Z})' = \mathrm{Gl}(2,\mathbb{Z})/\{\pm 1\} \simeq \mathrm{GP}(1,\mathbb{Z})) \simeq (\mathcal{T}'_{1,1} = \mathcal{T}_{1,1}/\{\pm 1\})$$

and on the "loop" automorphisms of $\widehat{\mathfrak{S}}^{+}_{0,3}$ and of $\widehat{\Pi}_{0,3}$ (Fundamental formulary).
m744

Marginal note. m744 d1 $\mathfrak{S}_{0,3}$ defined as $\mathrm{Aut}_{\mathrm{lac}}(\Pi_{0,3})$ — we give five different views of it ! (In fact, there are some ten of them, cf. (V) below…)

I) $\mathcal{T}_{0,3}$

The group $\mathfrak{S}_{0,3}$ is presented as an extension

$$(1) \qquad \begin{array}{ccccccccc} 1 & \longrightarrow & \Pi_{0,3} & \longrightarrow & \mathfrak{S}_{0,3} & \longrightarrow & \mathcal{T}_{0,3} & \longrightarrow & 1 \\ & & \| & & & & \wr & & \\ & & \Pi_1(U_{0,3}^{\mathrm{an}}; -\bar{j}) & & & & \mathfrak{S}_3 \times \mathbb{Z}/2\mathbb{Z} & & \end{array}$$

where $\mathfrak{S}_3 \times \mathbb{Z}/2\mathbb{Z}$ is regarded as a group operating on $U_{0,3}^{\mathrm{an}} = \mathbb{P}^{1\mathrm{an}} \setminus \{0,1,\infty\} = \mathbb{C} \setminus \{0,1\}$, d2 d3 — it is the group of conformal automorphisms of the|of $\mathbb{P}^{1\mathrm{an}}$ which stabilize $\{0,1,\infty\}$. The group d4$\mathfrak{S}_3 = \mathfrak{S}_{\{0,1,\infty\}}$ i1 is the subgroup of d5conformal automorphisms, it is identified with the group of permutations of $\{0,1,\infty\}$, its six elements are id;|1; $\dot{\sigma}_0, \dot{\sigma}_1, \dot{\sigma}_\infty$ (the three i2 transpositions), $\dot{\rho}, \dot{\rho}^{-1}$ (cyclic permutations) given by the explicit formulas (2)

$$(2) \qquad \begin{cases} \dot{\sigma}_0(z) = \dfrac{z}{z-1} = 1 + \dfrac{1}{1-z} \Big| = 1 + \dfrac{1}{z-1}, \quad \dot{\sigma}_1(z) = \dfrac{1}{z}, \quad \dot{\sigma}_\infty(z) = 1 - z, \\ \dot{\rho}(z) = \dfrac{1}{1-z}, \quad \dot{\rho}^{-1}(z) = 1 - \dfrac{1}{z} = \dfrac{z-1}{z}, \end{cases}$$

with

$$(3) \qquad \begin{cases} \dot{\sigma}_0\dot{\sigma}_1 = \dot{\sigma}_1\dot{\sigma}_\infty = \dot{\sigma}_\infty\dot{\sigma}_0 = \dot{\rho}, \\ \dot{\rho}\dot{\sigma}_0\dot{\rho}^{-1} = \dot{\sigma}_1, \quad \dot{\rho}\dot{\sigma}_1\dot{\rho}^{-1} = \dot{\sigma}_\infty, \quad \dot{\rho}\dot{\sigma}_\infty\dot{\rho}^{-1} = \dot{\sigma}_0 \end{cases}$$

$$(4) \qquad \dot{\sigma}_0^2 = \dot{\sigma}_1^2 = \dot{\sigma}_\infty^2 = \dot{\rho}^3 = 1.$$

The group $\mathcal{T}'_{0,3} = \mathbb{Z}/2\mathbb{Z} \subset \mathcal{T}_{0,3}$ appears as the center, 83

where $j = \exp 2i\pi/3 = \dfrac{-1 + i\sqrt{3}}{2}$ primitive root $3^{\text{ième|ème}}$ of 1

$-\bar j = \exp 2i\pi/6 = \dfrac{1 + i\sqrt{3}}{2}$ primitive root $6^{\text{ième|ème}}$ of 1

N.B. $\mathbb{P}^{1\,\dot\rho\tau}_{\mathbb{C}} = \mathbb{P}^{1\,\dot\rho^{-1}\tau}_{\mathbb{C}} = \emptyset$

$$(9) \qquad \begin{cases} \mathbb{P}^{1\,\tau}_{\mathbb{C}} = \mathbb{P}^1_{\mathbb{R}} \\ \mathbb{P}^{1\,\dot\tau_0'}_{\mathbb{C}} = \{x + iy \mid (x-1)^2 + y^2 = 1\} \\ \quad = \{z \mid z + \bar z = z\bar z\} = \frac{1}{z}| = \frac{1}{2} = \frac{1}{2} - \mathbb{U}, \\ \mathbb{P}^{1\,\dot\tau_1'}_{\mathbb{C}} = \{z \mid z\bar z = 1\} = \{x + iy \mid x^2 + y^2 = 1\} = \mathbb{U} \\ \mathbb{P}^{1\,\dot\tau_\infty'}_{\mathbb{C}} = \{z \mid z + \bar z = 1\} = \{x + iy \mid x = \frac{1}{2}\} = \frac{1}{2} + i\mathbb{R}; \end{cases}$$

The most suggestive picture is probably that of the Riemann sphere, where $\tau, \dot\tau_0', \dot\tau_1', \dot\tau_\infty'$ appear as the [d4]reflections[i4] with respect to the corresponding [d5]"gr[eat]|great circles"[i5], which for τ is "the equator" and for the others are the great circles "meridians"[i6], passing through the poles $-\bar j, -j$, which effect the cutting up of the equator into six circular segments, by the subdivision points $0, \frac{1}{2}, 1, 2, \infty, -1$.

Let us also note the formulas

$$(10)\qquad \begin{cases} \dot\rho\dot\tau'_0\dot\rho^{-1} = \dot\tau'_1, \quad \dot\rho\dot\tau'_1\dot\rho^{-1} = \dot\tau'_\infty, \quad \dot\rho\dot\tau'_\infty\dot\rho^{-1} = \dot\tau'_0 \\ \dot\tau'_0\dot\tau'_1 = \dot\tau'_1\dot\tau'_\infty = \dot\tau'_\infty\dot\tau'_0 = \dot\rho \end{cases}$$

[scan 86]

[p. 332]

The four great circles (9) cut the sphere into 12 spherical triangles, which form fundamental domains for the group $\mathcal{T}_{0,3} \simeq \mathfrak{S}_3 \times \mathbb{Z}/2$ of order 12, and are permuted among themselves in a simply transitive way. [d1](This is also|thus[i1] the barycentric subdivision of the double spherical triangles determined by the equator $\mathbb{P}^1_{\mathbb{R}}$, and its three subdivision points $0, 1, \infty$.) Let us take one of these spherical triangles, say $(-\bar{j}, 0, \frac{1}{2})$, the reflections with respect to its three[i2] sides, i.e. $\tau, \dot{\tau}'_\infty, \dot{\tau}'_0$, form a system of generators of $\mathcal{T}_{0,3}$, with the relations

$$(11) \qquad \tau^2 = \dot{\tau}'^2_\infty = \dot{\tau}'^2_0 = \left(\underbrace{\tau\dot{\tau}'_\infty\tau}_{\dot{\sigma}_\infty}\right)^2 = \left(\underbrace{\dot{\tau}'_0\dot{\tau}'_\infty}_{\dot{\rho}^{-1}}\right)^3 = \left(\underbrace{\tau\dot{\tau}'_0}_{\dot{\sigma}_0}\right)^2 = 1$$

as for $\mathfrak{S}_3 = \mathcal{T}^+_{0,3}$, it is generated by $\tau\dot{\tau}'_\infty = \dot{\sigma}_\infty$, $\dot{\tau}'_0\dot{\tau}'_\infty = \dot{\rho}^{-1|1}$ and $\tau\dot{\tau}'_0 = \dot{\sigma}_0$, with the relations

$$(12) \qquad \dot{\sigma}_0\dot{\rho}\dot{\sigma}_\infty = \dot{\sigma}^2 = \dot{\rho}^3 = \dot{\sigma}_0^2 = 1.$$

II) The group $\Pi_{0,3}$ is generated by $\ell_0, \ell_1, \ell_\infty$, linked by the generating relation

$$(13) \qquad \ell_\infty\ell_1\ell_0 = 1$$

The [d3] subgroup of index 2[i3] $\mathfrak{S}'_3 = (\mathcal{T}_{0,3})_{-\bar{j}} = \mathcal{T}_{0,3}$, stabilizer of $-\bar{j}$, consisting of the $(g, \tau^\varepsilon) \in \mathfrak{S}_3 \times \mathbb{Z}/2\mathbb{Z}$ such that $\mathrm{sg}(g) = (-1)^\varepsilon$, operates on $\Pi_{0,3}$. This subgroup consists of $1, \dot{\tau}_0, \dot{\tau}_1, \dot{\tau}_\infty, \dot{\rho}, \dot{\rho}^{-1}$, and their operations on $\Pi_{0,3}$ are denoted respectively $1, \tau'_0, \tau'_1, \tau'_\infty, \rho, \rho^{-1}$.

m749

Marginal note. [m749] N.B. $\tau'_0, \tau'_1, \tau'_\infty$ were previously denoted (in [C]) $\sigma_0, \sigma_1, \sigma_\infty|\bar{\sigma}_0, \bar{\sigma}_1, \bar{\sigma}_\infty$.

[scan 87]

[d1] [d2] We identify these elements [d3] with elements of the[i1] group $\mathrm{Aut}_{\mathrm{lac}}(\Pi_{0,3}) \simeq \mathfrak{S}_{0,3}$, [d4] hence [d5] for $g \in \mathfrak{S}'_3$, $x \in \Pi_{0,3}$, we set $g(x) = gxg^{-1}$; and we find:

$$(14) \qquad \begin{cases} \rho(\ell_0) = \rho\ell_0\rho^{-1} = \ell_1, & \rho(\ell_1) = \rho\ell_1\rho^{-1} = \ell_\infty, & \rho(\ell_\infty) = \rho\ell_\infty\rho^{-1} = \ell_0, \\ \dot{\tau}'_0|\tau'_0(\ell_0) = \ell_0^{-1}, & \dot{\tau}'_0|\tau'_0(\ell_1) = \ell_\infty^{-1}, & \dot{\tau}'_0|\tau'_0(\ell_\infty) = \ell_1^{-1}, \\ \tau'_1(\ell_1) = \ell_1^{-1}, & \tau'_1(\ell_\infty) = \ell_0^{-1}, & \tau'_1(\ell_0) = \ell_\infty^{-1}, \\ \tau'_\infty(\ell_\infty) = \ell_\infty^{-1}, & \tau'_\infty(\ell_0) = \ell_1^{-1}, & \tau'_\infty(\ell_0|\ell_1|\ell_\infty) = \ell_1^{-1} \end{cases}$$

: $\tau'_0\tau'_1 = \tau'_1\tau'_\infty = \tau'_\infty\tau'_0 = \rho$ (and of course we have $\tau'^2_0 = \tau'^2_1 = \tau'^2_\infty|\tau^2_\infty = \rho^3 = 1$). (15)

In[i3] The group $\mathfrak{S}_{0,3}$ we define elements $\sigma_0, \sigma_1, \sigma_\infty$, over $\dot\sigma_0, \dot\sigma_1, \dot\sigma_\infty$, by

$$\begin{cases} \sigma_0(\ell_1) = \ell_\infty, & \sigma_0(\ell_\infty) = \ell_1, & \sigma_0(\ell_0) = (\ell_1\ell_\infty)^{-1} \\ \sigma_1(\ell_\infty) = \ell_0, & \sigma_1(\ell_0) = \ell_\infty, & \sigma_1(\ell_1) = (\ell_\infty\ell_0)^{-1} \\ \sigma_\infty(\ell_0) = \ell_1, & \sigma_\infty(\ell_1) = \ell_0, & \sigma_\infty(\ell_\infty) = (\ell_0\ell_1)^{-1} \end{cases} \tag{16}$$

We have

$$\begin{cases} \rho\sigma_0\rho^{-1} = \sigma_1, & \rho\sigma_1\rho^{-1} = \sigma_\infty, & \rho\sigma_\infty\rho^{-1} = \sigma_0 \\ \rho\tau_0\rho^{-1} = \tau_1, & \rho\tau_1\rho^{-1} = \tau_\infty, & \rho\tau_\infty\rho^{-1} = \tau_0 \end{cases}, \tag{17}$$

$$\sigma_0\sigma_1 = \rho\ell_0 = \ell_1\rho, \quad \sigma_1\sigma_\infty = \rho\ell_1 = \ell_\infty\rho, \quad \sigma_\infty\sigma_0 = \rho\ell_\infty = \ell_0\rho^{-1}. \tag{18}$$

m751

Marginal note. [m751] N.B. $\sigma_0, \sigma_1, \sigma_\infty \in \mathfrak{S}^+_{0,3}$, $\tau'_0, \tau'_1, \tau'_\infty \in \mathfrak{S}^-_{0,3}$, $\tau_0, \tau_1, \tau_\infty \in \mathfrak{S}^-_{0,3}$.

We thus have elements of $\mathfrak{S}_{0,3}$ on top of|of the $1, \dot\sigma_0, \dot\sigma_1, \dot\sigma_\infty, \dot\rho, \dot\rho^{-1}, \dot\tau'_0, \dot\tau'_1, \dot\tau'_\infty$, but not yet over τ (which makes it possible to have some over $\tau\dot\rho, \tau\dot\rho^{-1}$), we set $\tau_i = \underbrace{\sigma_i}_{\text{over } \dot\sigma_i} \underbrace{\tau'_i}_{\text{over } \dot\tau'_i} = \tau'_i\sigma_i$[i4] (which is over τ, [d7] [d8] τ_i is characterized [d9] by the condition of being over τ, of square 1,[i5] and of commuting with σ_i (or again, with τ'_i) [m752]

Marginal note. [m752] recall why we have this characterization.

$$[\tau_0, \sigma_0] = [\tau_1, \sigma_1] = [\tau_\infty, \sigma_\infty] = 1 \tag{19}$$

m753

Marginal note. [m753] $\tau_0 = \sigma_0\tau'_0 = \tau'_0\sigma_0$ $\quad \tau_1 = \sigma_1\tau'_1 = \tau'_1\sigma_1$ $\quad \tau_\infty = \sigma_\infty\tau'_\infty = \tau'_\infty\sigma_\infty$

$$\tau_0^2 = \tau_1^2 = \tau_\infty^2 = 1 \qquad \text{and } \tau_0, \tau_1, \tau_\infty \text{ over } \tau. \tag{20}$$

We find

$$\tau_\infty\tau_1 = \ell_0, \quad \tau_0\tau_\infty = \ell_1, \quad \tau_1\tau_0 = \ell_\infty. \tag{21}$$

To do things properly, we should make explicit the topological description (given in [C]) of $\sigma_0, \sigma_1, \sigma_\infty, \rho, \tau'_0, \tau'_1, \tau'_\infty, \tau_0, \tau_1, \tau_\infty$. 86

[scan 88]

[p. 333]

We have

$$\begin{cases} (\sigma_\infty \rho)^2 = (\rho\sigma_1)^2 = \ell_0 = \varepsilon_0^2, & \varepsilon_0 \overset{\text{definition|definition}}{=} \sigma_\infty \rho = \rho\sigma_1 \\ & (\text{NB } \sigma_\infty = \rho\sigma_1\rho^{-1}) \\ (\sigma_0\rho)^2 = (\rho\sigma_\infty)^2 = \ell_1 = \varepsilon_1^2, & \varepsilon_1 = \sigma_0\rho = \rho\sigma_\infty \\ (\sigma_1\rho)^2 = (\rho\sigma_\infty|\sigma_0)^2 = \ell_\infty = \varepsilon_\infty^2, & \varepsilon_\infty = \sigma_1\rho = \rho\sigma_0 \end{cases} \tag{22}$$

The element $\varepsilon_i \in \mathfrak{S}_{0,3}$ (in fact $\varepsilon_i \in \mathfrak{S}^+_{0,3}$) is over $\dot\sigma_i$, it is characterized by the condition

$$\varepsilon_i^2 = \ell_i.$$

In the group $\mathcal{T}_{0,3}$ of order 12, there are seven involutive elements $\dot\sigma_0, \dot\sigma_1, \dot\sigma_\infty, \tau, \dot\tau_0', \dot\tau_1', \dot\tau_\infty'$, [d2] two[i1] elements of order 3 $\dot\rho, \dot\rho^{-1}$, and two of order 6[i2] $\dot\rho\tau, \dot\rho^{-1}\tau$ (in addition to the identity).

Except for the last two (for which this is not possible*)[i3] We have lifted each of these elements to elements of the same order in $\mathfrak{S}_{0,3}$. We know that the possibilities, mod $\Pi_{0,3}$-conjugation, of|of the such liftings, correspond to the connected components of the fixed points in|of $U = U^{\text{an}}_{0,3}$ of the corresponding topological automorphisms. — for $\dot\sigma_0, \dot\sigma_1, \dot\sigma_\infty, \dot\tau_0', \dot\tau_1', \dot\tau_\infty'$ there is only one possibility mod conjugation (we have chosen $\sigma_0, \sigma_1, \sigma_\infty, \tau_0, \tau_1, \tau_\infty$ in the way that seemed most convenient for the calculations), for τ there are three — these are the three choices $\tau_0, \tau_1, \tau_\infty$ — for $\dot\rho, \dot\rho^{-1}$ there are two, corresponding|corresponding to the two poles $-\bar j, -j$ — we have chosen the one that corresponds to the pole $-\bar j$. The liftings corresponding to $-j$ can be deduced from them by conjugating by a τ_i:

* indeed $\mathbb{P}^{1\,\dot\rho\tau} = \mathbb{P}^{1\,\dot\rho^{-1}\tau} = \emptyset$

$$(23)\qquad \rho_0 = \tau_0\rho\tau_0^{-1} = \ell_\infty^{-1}\rho = \rho\ell_1^{-1}, \qquad \rho_1 = \tau_1\rho\tau_1^{-1} = \ell_0^{-1}\rho = \rho\ell_\infty^{-1},$$
$$\rho_\infty = \tau_\infty\rho\tau_\infty^{-1} = \ell_1^{-1}\rho = \rho\ell_0^{-1}$$

are of order 3, over $\dot\rho$, and $\Pi_{0,3}$-conjugate to one another*, but not $\Pi_{0,3}$-conjugate to ρ. m757

Marginal note. m757 * N.B.

$$\rho\rho_0\rho^{-1} = \rho_1$$
$$\rho\rho_1\rho^{-1} = \rho_\infty$$
$$\rho\rho_\infty\rho^{-1} = \rho_0$$

Let us also note d1 the corollary formulas of the general theory – and of the fact that the connected components of the sets of fixed points which appear here are 1-connected –

$$(24)\qquad \Pi_{0,3}^{\sigma_i} = \Pi_{0,3}^{\rho} = \Pi_{0,3}^{\tau_i} = \Pi_{0,3}^{\tau_i'} = \{1\}$$

If we look at the critical points of $U_{0,3}^{\text{an}}$, relative to the operation of $\mathcal{T}_{0,3}$, we find the d2two orbits[i4] $(2, -1, \frac{1}{2})$ and $(-\bar j, -j)$, the stabilizer of a point of these orbits is of order 4 resp. 6. For the point 2 (opposite 0), this stabilizer is the group $\mathrm{D}_2 \simeq \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, generated by $\dot\sigma_0, \dot\tau_0$ (or σ_0, τ_0') – which has indeed been lifted multiplicatively to $\mathfrak{S}_{0,3}$. Likewise|=, for the point $-\bar j$, it is $\mathfrak{S}_3' \simeq \mathrm{D}_3$, which has also been lifted. By the general theory we know that the $\Pi_{0,3}$-conjugacy classes of such a lifting correspond to the fixed points of the group of operators under consideration[i6] on $U_{0,3}$, for $\mathrm{D}_2^{(0)}$ there is only one fixed point, namely 2, for $\mathfrak{S}_3' = \mathrm{D}_3$ there are two, $-\bar j$ and $-j$, we had chosen $-\bar j$. We find|will find the other conjugacy class 88

[scan 90]

[p. 334]

by conjugating by any one of the τ_i $(\tau_0, \tau_1, \tau_\infty)$.

III Relation with the unoriented triangul- cartographic group,

$$\begin{aligned}\widetilde{\Pi}'_{0,3} &= \Pi_1(\mathbb{P}^{1\circ}_{\mathbb{C}} | \mathbb{P}^{1\bullet}_{\mathbb{C}},\ 0\{0\} + 2\{1\} + 3\{\infty\}; -\bar{j}) \\ &= (\Pi_{0,3} \cdot \{1, \tau\})/(\ell_1^2, \ell_\infty^3),\end{aligned}$$

and with $\mathrm{Sl}(2, \mathbb{Z})$.

We have [d1] involutive[i1] generators $\sigma_0, \sigma_1, \sigma_2$ of $\widetilde{\Pi}'_{0,3}$, (σ_i in a map frame [d2]changes[i2] the [d3]of dimension i[i3] of the frame, so for a biarc σ_0 and σ_2 are resp. the [d4]change[s] of orientation[i4] tangential|tangential resp. transverse, σ_1 the passage to the "adjacent" biarc

) with the generating relations

$$(25) \qquad \begin{cases} (\sigma'_0)^2 = (\sigma'_1)^2 = (\sigma'_2)^2 = (\sigma'_2\sigma'_0)^2 = 1 \\ \underbrace{(\sigma'_1\sigma'_0)}_{\rho_f}{}^3 = 1 \end{cases}$$

m759

Marginal note. [m759] we could also write σ'_∞ instead of σ'_2. We would have done better to denote them here[i5] outright r_0, r_1, r_∞ (instead of $\sigma_0, \sigma_1, \sigma_2$).

The subgroup $\Pi'_{0,3}$[i6] of index 2 [d5](oriented triangul' cartographic group)[i7] is generated by

$$\sigma'_1\sigma'_0 = \rho_f = \ell'_\infty, \qquad \sigma'_2\sigma'_1 = \rho_s = \ell'_0, \qquad \sigma'_0\sigma'_2 = \sigma' | \sigma = \ell'_1,$$

with the generating relations

$$(26) \qquad \rho_f\sigma\rho_s = 1 \qquad \sigma^2 = \rho_f^3 = 1$$

This is therefore the quotient of $\Pi_{0,3}$ by ℓ_1^2, ℓ_∞^3

$$(27|17) \qquad \begin{cases} \Pi_{0,3} & \longrightarrow & \Pi'_{0,3} \\ \ell_0 & \longmapsto & \ell'_0 = \rho_s \\ \ell_1 & \longmapsto & \ell'_1 = \sigma \\ \ell_\infty & \longmapsto & \ell'_\infty = \rho_f \end{cases} ,$$

Scans 91–110

[scan 91]

$$(28)\qquad \begin{cases} \widetilde{\Pi}_{0,3} = \Pi_{0,3} \cdot \{1, \tau\} \longrightarrow \widetilde{\Pi}'_{0,3} \\ \qquad\qquad \tau_0, \tau_1, \tau_\infty \longmapsto \sigma'_0, \sigma'_1, \sigma'_\infty \end{cases}$$

This being so, we define an isomorphism [d1]

$$\widetilde{\Pi}'_{0,3} \xrightarrow{\sim} \mathfrak{S}_{0,3}$$

$$(29)\qquad (\sigma'_0, \sigma'_1, \sigma'_\infty) \longrightarrow \left(\begin{array}{ccc} \tau'_\infty & , \quad \tau'_0 & , \quad \tau_\infty \\ \text{over } \dot\tau'_\infty & \text{over } \dot\tau'_0 & \text{over } \tau \\ \| & \| & \\ \dot\sigma_\infty \tau & \dot\sigma_0 \tau & \end{array} \right)$$

also denoted r_0, r_1, r_∞ (fundamental reflections)
m761

Marginal note. [m761] This isomorphism is associated with a canonical homomorphism $\varphi : \widetilde{\Pi}_{0,3} = \Pi_{0,3} \cdot \{1, \tau\} \xrightarrow{\text{epimorphism}} \mathfrak{S}_{0,3}$ inducing a canonical homomorphism $\varphi : \Pi_{0,3} \xrightarrow{\text{epimorphism}} \mathfrak{S}^+_{0,3}$ allowing us to identify $\mathfrak{S}_{0,3}$ and $\mathfrak{S}^+_{0,3}$ with the quotients of the left-hand sides|sides by the relations $\ell_1^2 = \ell_\infty^3 = 1$ …

which induces an isomorphism

$$(30)\qquad \begin{cases} \Pi'_{0,3} \xrightarrow{\sim} \mathfrak{S}^+_{0,3} \\ \rho_s = \ell'_0 \longmapsto \varepsilon_0 = \sigma_\infty \rho \\ \sigma = \ell'_1 \longmapsto \sigma_\infty \\ \rho_f = \ell'_\infty \longmapsto \rho^{-1} \end{cases}$$

m762

Marginal note. [m762] N.B. $\begin{cases} \tau_\infty \tau'_0 = \varepsilon_0 = \ell'_0 \\ \tau'_\infty \tau_\infty = \sigma_\infty = \ell'_1 \\ \tau'_0 \tau'_\infty = \rho^{-1} = \ell'_\infty \end{cases}$ i.e. $\begin{array}{r} r_\infty r_1 = \ell'_0 \ (= \varepsilon_0) \\ r_0 r_\infty = \ell'_1 \ (= \sigma_\infty) \\ r_1 r_0 = \ell'_\infty \ (= \rho^{-1}) \end{array}$

We thus find that $\mathfrak{S}_{0,3}$ has [d4] generating relations

$$(31)\qquad {\tau'_\infty}^2 = {\tau'_0}^2 = \tau_\infty^2 = \underbrace{(\tau'_\infty \tau_\infty)}_{\sigma_\infty}{}^2 = \underbrace{(\tau'_0 \tau'_\infty)}_{\rho^{-1}}{}^3 = 1,$$

and $\mathfrak{S}^+_{0,3}$ has generating relations

$$(32)\quad \ell'_\infty \ell'_1 \ell'_0 = {\ell'_1}^2 = {\ell'_\infty}^3 = 1$$

or also simply, eliminating ℓ'_0 and setting $\ell'_1 = \sigma_\infty$ and ${\ell'_\infty}^{-1} = \rho$

$$(33)\quad \boxed{\sigma_\infty^2 = \rho^3 = 1}$$

For the record, we are going to express the notable elements of $\mathfrak{S}^+_{0,3}$ in terms of σ_∞, ρ:

[scan 92]

[p. 335]

$$(34)\quad \begin{cases} \varepsilon_0 = \sigma_\infty \rho & \ell_0 = \sigma_\infty \rho \sigma_\infty \rho = (\sigma_\infty \rho)^2 \\ \varepsilon_1 = \rho \sigma_\infty & \ell_1 = \rho \sigma_\infty \rho \sigma_\infty = (\rho \sigma_\infty)^2 \\ \varepsilon_\infty = \rho^{-1} \sigma_\infty \rho^{-1} & \ell_\infty = (\rho^{-1} \sigma_\infty \rho^{-1})^2 = \rho^{-1} \sigma_\infty \rho^{-1} \sigma_\infty \rho^{-1} \end{cases},$$

$$(35)\quad \begin{cases} \sigma_0 = \rho \sigma_\infty \rho^{-1} & (= \varepsilon_1 \rho^{-1} = \rho \varepsilon_1^{-1}) \\ \sigma_1 = \rho^{-1} \sigma_\infty \rho & (= \rho^{-1} \varepsilon_0 = \varepsilon_\infty \rho^{-1}) \end{cases}$$

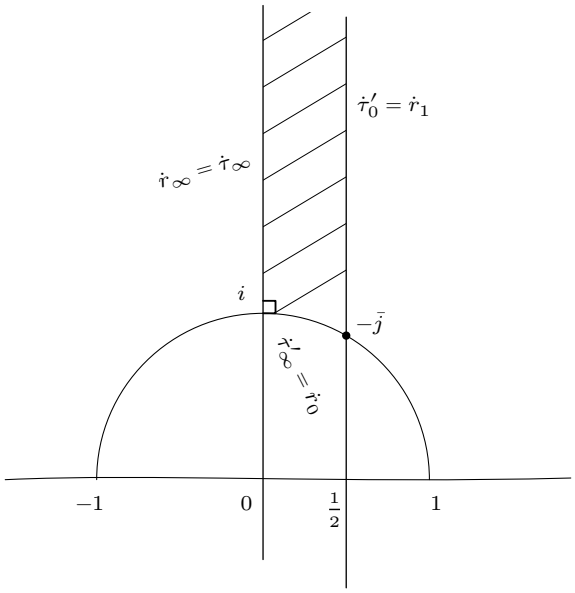
and in $\mathfrak{S}^-_{0,3}$ we have, in terms of $\tau'_\infty, \tau'_0, \tau_\infty$, the expressions for [d7] $\tau_0, \tau_1, (\tau_\infty, \tau'_0), \tau'_1, (\tau'_\infty)$[i1]

$$(36)\quad \begin{cases} \tau_0 = \rho \tau_\infty \rho^{-1} = \tau'_\infty \tau'_0 \tau_\infty \tau'_0 \tau'_\infty & (= r_0 r_1 r_\infty r_1 r_0) \\ \tau_1 = \rho^{-1} \tau_\infty \rho = \tau'_0 \tau'_\infty \tau_\infty \tau'_\infty \tau'_0 & (= r_1 r_0 r_\infty r_0 r_1) \\ \tau'_1 = \rho \tau'_0 \rho^{-1} = \tau'_\infty \tau'_0 \tau'_\infty & (= r_0 r_1 r_0) \end{cases}$$

and

$$\begin{cases} \tau'_\infty = r_0 \\ \tau'_0 = r_1 \\ \tau_\infty = r_\infty . \end{cases}$$

IV) Relation with $\mathrm{Gl}(2,\mathbb{Z})' = \mathrm{Gl}(2,\mathbb{Z})/\pm 1 \simeq \mathrm{GP}(1,\mathbb{Z})$.
This group operates on the Poincaré half-plane



$$D = \{z \in \mathbb{C} \mid \Im z > 0\}$$

by

$$(37) \quad \begin{cases} u_g(z) = \dfrac{az+b}{cz+d} & \text{if } ad-bc = +1 \\ u_g(z) = \dfrac{a\bar{z}+b}{c\bar{z}+d} & \text{if } ad-bc = -1 \end{cases} \qquad \begin{matrix} g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \\ a,b,c,d \in \mathbb{Z} \\ ad-bc \in \{\pm 1\} \end{matrix}$$

We have in D a hatched fundamental domain, which corresponds to the spherical triangle $(-\bar{j}, 0, \frac{1}{2})$ by the homomorphism|homeomorphism of the natural covering, i corresponding to $\frac{1}{2}$, $-\bar{j}$ to $-\bar{j}$, and the point at infinity to 0. [d10]The reflections[i2] with respect to the three sides of this triangle are given by

$$(38) \quad r_0|\tau_0(z) = \frac{1}{\bar{z}}, \qquad r_1|\tau_1(z) = 1-\bar{z}, \qquad r_\infty|\tau_\infty(z) = -\bar{z}$$

[d12] and the pairwise products of these reflections

[scan 95]

It makes our hands|our hand itch to [d1]work[i1] in $\mathrm{Gl}(2,\mathbb{Z})$ itself, a central extension of $\mathfrak{S}_{0,3}$ — in fact, this extension is interpreted as $\mathcal{T}_{1,1}$ — but we shall come back to it, later…

V) Let us sum up the avatars of the same group, which we have encountered|encountered so far

1) $\mathfrak{S}_{0,3} \overset{\text{dfn}}{=} \mathrm{Aut}_{\mathrm{lac}}(\Pi_{0,3})$ with subgroup $\mathfrak{S}^{+}_{0,3}$ (preserving orientation)

2) $\mathcal{T}'_{0,4} \simeq \mathrm{Autext}_{\mathrm{lac}}(\Pi_{0,4})'$ outer automorphisms of $\Pi_{0,4}$ respecting the loop structure and fixing the loop class $L_4|L_\lambda$ (and permuting $L_0, L_1, L_\infty|L_3$)

[d2] [d3] with $\mathcal{T}'^{+}_{0,4}$ (preserving orientation)

3) $A'_{0,4}/A'^{0}_{0,4}$ group of connected components of

$$A'_{0,4} \subset \mathrm{Auttop}\left(\begin{array}{c} U^{\mathrm{top}}_{0,4} \\ \| \\ \mathbb{P}^1_{\mathbb{C}}\setminus\{0,1,\infty;\frac{1}{2}\} \end{array}\right)$$

subgroup of automorphisms that fix the point at infinity $a_{0,4} = \frac{1}{2}$

with $A'^{+}_{0,4}/A'^{0}_{0,4}$ (preserving orientation

4) $\Pi_1((U^{\mathrm{an}}_{0,3}, \overbrace{\mathfrak{S}_3 \times \mathbb{Z}_2|\mathbb{Z}/2}^{\mathcal{T}_{0,3}}), -\bar{j})$ (described in the manner of J. Malgoire) with the subgroup $\Pi_1((U^{\mathrm{an}}_{0,3}, \mathfrak{S}_3), -\bar{j})$ ($\mathfrak{S}_3 = \mathcal{T}^{+}_{0,3}$)

5) $\Pi_1((\mathbb{P}^{1\,\mathrm{an}}_{\mathbb{C}}, 0\cdot\{0\} + 2\{1\} + 3\{\infty\}), -\bar{j})$ (in the manner of J. Malgoire) with the subgroup $\Pi_1(\mathbb{P}^{1\,\mathrm{an}}_{\mathbb{C}}, 0\{0\} + 2\{1\} + 3\{\infty\})$

6) Triangulated cartographic group [d5] $\Gamma_{\infty,3}$

$$\Gamma_{\infty,3}\} = \{r_0, r_1, r_\infty \mid r_0^2 = r_1^2 = r_\infty^2 = (r_0 r_\infty)^2 = (r_1 r_0)^3 = 1\}$$

(with oriented triangulated cartographic subgroup

$$\Gamma^{\circ}_{\infty,3} = \{\ \underset{\| \\ r_\infty r_1}{\rho_s}\ ,\ \underset{\| \\ r_0 r_\infty}{\sigma}\ ,\ \underset{\| \\ r_1 r_0}{\rho_f}\ \mid \rho_f\sigma\rho_s = \sigma^2 = \rho_f^3 = 1\}.$$

)

m766

Marginal note. [m766] this is also the group $\widetilde{\Pi}_{0,3}/(\ell_1^2, \ell_\infty^3)$, where $\widetilde{\Pi}_{0,3} = \Pi_{0,3}\cdot\{1,\tau\}$

7) $\Pi_1(\mathcal{U}^{\mathrm{conf}}_{0,3}, \mathrm{pt}(U_{0,3}, -\bar{j}))$ universal conformal surface of type $(0,3)$[i2] with subgroup $\Pi_1(\mathcal{U}^{\mathrm{an}}_{0,3}, \mathrm{pt}(U_{0,3}, -\bar{j}))$ universal holomorphic surface of type $(0,3)$[i3]

m767

Marginal note. [m767] N.B. $\mathcal{U}^{\mathrm{conf}}_{0,3} \simeq (U_{0,3}, \mathcal{T}_{0,3})$ which makes it possible to identify 7) with 4)

8) $\mathcal{T}'_{1,1} = \mathcal{T}_{1,1}/\underbrace{\{\pm 1\}}_{\text{center}}$, with $\mathcal{T}_{1,1} \simeq \mathrm{Autext}_{\mathrm{lac}}(\Pi_{1,1}) \simeq A_{1,1}/A^0_{1,1}$

($A_{1,1} \simeq$ topological automorphisms of $U^{\circ}_{1,1}|U_{1,1}$) with subgroup $\mathcal{T}'^{+}_{1,1} = \mathcal{T}^{+}_{1,1}/\{\pm 1\}$

[scan 97]

(VI) The loop automorphisms of $\widehat{\Pi}_{0,3}$ and of $\widehat{\mathfrak{S}}^{+}_{0,3}$

We have a canonical commutative diagram:

(49)

$$\begin{array}{ccc}
\begin{array}{l}\mathrm{Autext}(\widehat{\mathfrak{S}}^{+}_{0,3})'\\ =\text{ group of outer automorphisms}\\ \text{inducing}\\ \text{the identity in the}\\ \text{quotient } \mathfrak{S}_3 \simeq \mathcal{T}^{+}_{0,3}\end{array} & \xrightarrow[\sim]{\text{restriction}} & \begin{array}{l}\mathrm{Autext}^{\rho}(\widehat{\Pi}_{0,3})'\\ =\text{ group of outer automorphisms}\\ \text{that}\\ \text{commute with}\\ \text{the outer action of } \mathfrak{S}_3\end{array}\\
\uparrow \sim & & \uparrow \sim\\
\begin{array}{l}\mathrm{Aut}(\widehat{\mathfrak{S}}^{+}_{0,3}, \sigma_\infty)'\\ =\text{ group of automorphisms}\\ \text{of } \widehat{\mathfrak{S}}^{+}_{0,3} \text{ that fix } \sigma_\infty,\\ \text{and that fix } \rho \bmod \widehat{\Pi}_{0,3}\end{array} & \xrightarrow[\sim]{\text{restriction}} & \begin{array}{l}\mathrm{Aut}(\widehat{\Pi}_{0,3}, \sigma_\infty)\\ =\text{ group of automorphisms}\\ \text{that commute}\\ \text{with } \sigma_\infty, \text{ and that}\\ \text{commute}\\ \text{ext}^{\mathrm{t}}.\text{ with } \rho\end{array}
\end{array}$$

The $\in$ [d3] $\mathrm{Aut}(\widehat{\mathfrak{S}}^{+}_{0,3}, \sigma_\infty)'$ are of the form

$$(50) \qquad \begin{cases} u(\sigma_\infty) = \sigma_\infty \\ u(\rho) = g\rho \end{cases} \qquad (\text{i.e. } u\rho u^{-1}\rho^{-1} = g)$$

m769

Marginal note. [m769] We write the formulas in $\mathrm{Aut}(\widehat{\mathfrak{S}}^{+}_{0,3})' = G$, group of automorphisms of $\widehat{\mathfrak{S}}^{+}_{0,3}$ that induce the identity in $\widehat{\mathfrak{S}}^{+}_{0,3}/\Pi_{0,3} \simeq \mathfrak{S}_3$, is identified with the group $\mathrm{Aut}(\Pi_{0,3})' =$ gr. of automorphisms of $\Pi_{0,3}$ that commute outer[i2] with $\mathfrak{S}_3$; – we shall have $\Pi_{0,3} \subset \widehat{\mathfrak{S}}^{+}_{0,3} \subset \widehat{\mathfrak{S}}_{0,3} \subset \mathfrak{g}.|g.\, G$. N.B. We assume here that the center of $\widehat{\mathfrak{S}}^{+}_{0,3}$ is trivial.

$g \in \widehat{\Pi}_{0,3}$ [d4] is subject to the cocycle condition

$$(51) \qquad \boxed{g\rho(g)\rho^2(g) = 1}$$

which expresses the relation

$$(52) \qquad (g\rho)^3 = 1 \ .$$

We thus find a $1-1$ correspondence between the elements of $\mathrm{Aut}(\widehat{\mathfrak{S}}^+_{0,3}, \sigma_\infty)'$ and the $g \in \widehat{\Pi}_{0,3}$ satisfying (51), and such moreover that

(53) $\sigma_\infty, g\rho$ with the relations $\sigma_\infty^2 = (g\rho)^3 = 1$ present $\widehat{\mathfrak{S}}^+_{0,3}$

[scan 98]

[p. 338]

(which I am going to call the "preliminary condition").
d1

For a $u \in G = \mathrm{Aut}(\widehat{\mathfrak{S}}^+_{0,3})'$! (not necessarily fixing σ_∞), we have equivalent conditions

$$(54) \quad \begin{cases} \text{(i)} & u(\ell_0') \in \text{conjugate of } \varepsilon_0^{\widehat{\mathbb{Z}}} = L_0' \text{ (in } \widehat{\mathfrak{S}}^+_{0,3}) \\ \text{(ii)} & u(\ell_0) \in \text{conjugate of } \ell_0^{\widehat{\mathbb{Z}}} = L_0 \text{ (in } \widehat{\Pi}_{0,3}) \\ \text{(iii)} & u(L_i) \text{ conjugate of } L_i \quad \text{for } i = 0, 1, \infty \\ \text{(iv)} & \exists\ p \in \widehat{\mathbb{Z}}^*,\ g_0 \in \widehat{\Pi}_{0,3} \quad \boxed{u(\varepsilon_0) = \mathrm{int}(g_0)\varepsilon_0^p} \\ \text{(v)} & \exists\ p \in \widehat{\mathbb{Z}}^*,\ g_0 \in \widehat{\Pi}_{0,3} \quad \boxed{u(\ell_0) = \mathrm{int}(g_0)(\ell_0^p)} \end{cases}$$

We shall then also have

$$(55) \qquad \begin{array}{ll} u(\ell_1) = \mathrm{int}(g_1)(\ell_1^p) & g_1 = g\rho(g_0) \\ u(\ell_\infty) = \mathrm{int}(g_\infty)(\ell_\infty^p) & g_\infty = g\rho(g_1) = g\rho(g)\rho^2(g_0) \ . \end{array}$$

The element d4

$$(55) \qquad p \in \widehat{\mathbb{Z}}^* \qquad p = \chi(u)$$

is well determined by u, hence by g(if u given by (50))i2, we shall call it the multiplier of u. The element d5

$$(56) \qquad g_0 \in \widehat{\Pi}_{0,3}$$

is determined a priori modulo $L_0 = \ell_0^{\widehat{\mathbb{Z}}}$ (change

$$g_0 \longmapsto g_0 \ell_0^{\alpha} \tag{57}$$

).

m770

Marginal note. m770 Notations $\mathrm{Autext}_{\mathrm{lac}}(\widehat{\mathfrak{S}}^{+}_{0,3})$, $\mathrm{Aut}_{\mathrm{lac}}(\widehat{\mathfrak{S}}^{+}_{0,3})$, $\mathrm{Aut}_{\mathrm{lac}}(\widehat{\mathfrak{S}}^{+}_{0,3})'$, $\mathrm{Aut}_{\mathrm{lac}}(\widehat{\mathfrak{S}}^{+}_{0,3}, \sigma_\infty)'$, $\mathrm{Aut}_{\mathrm{lac}}(\widehat{\Pi}_{0,3}, \sigma_\infty)$ ...

If the equivalent[i3] conditions (54|55) are satisfied, we say that u respects the loop structure of $\widehat{\mathfrak{S}}^{+}_{0,3}$ (or of $\Pi_{0,3}$) – it being understood that $\widehat{\mathfrak{S}}^{+}_{0,3}$ is equipped with the "loop-group" $\varepsilon_0^{\widehat{\mathbb{Z}}} \simeq L_0'$. We shall restrict|restrict ourselves from now on to such automorphisms. N.B. These conditions depend only on the outer automorphism defined by u, in $\widehat{\Pi}_{0,3}$ or in $\widehat{\mathfrak{S}}^{+}_{0,3}$. We

[scan 99]

are going to take an interest in the canonical liftings of such outer automorphisms given by (49), (50), to actual automorphisms.

The defining formula (50) for u involves only $g \in \widehat{\Pi}_{0,3}$[i1], in principle g_0 mod L_0 in $\widehat{\Pi}_{0,3}/L_0$ is deduced from g. But in practice g_0 plays as important a role as g – we shall see that to a large extent it determines g (formula (62)).

If there were no need to introduce g_0, to express the conditions (54), we could easily parametrize the g satisfying (51) – hence corresponding to [d1]liftings of[i2] $\dot{\rho} \in \mathfrak{S}_3$ to elements of order 3 of $\widehat{\mathfrak{S}}^{+}_{0,3}$ – by noting that there are exactly two conjugacy classes of such liftings,

(corresponding to the fixed points $-\bar{j}, -j$ of $\dot{\rho}$ operating on $U^{\mathrm{an}}_{0,3}$), which are parametrized by

$$(58)\qquad \begin{cases} g = \lambda_0^{\sharp|*}\rho(\lambda_0^{\sharp|*})^{-1} = [\lambda_0^{\sharp|*}, \rho] & \text{(principal class, corresponding|corresponding to the “north pole” } -\bar{j}) \\ g = \lambda_0^{\sharp|*\prime}\ell_1^{-1}\rho(\lambda_0^{\sharp|*\prime})^{-1} & \text{(adjoint class, corresponding to the “south pole” } -j) \end{cases}$$

m771

Marginal note. m771 These|The parametric representations are unambiguous|unique.

where $\lambda_0, \lambda_0^{\sharp|*\prime} \in \widehat{\Pi}_{0,3}$. We shall see below that these cases correspond respectively to the cases

$$(59)\qquad p \equiv 1\ (3) \qquad \text{and} \qquad p \equiv -1\ (3)\ .$$

[scan 100]

[p. 339]

But here the situation gets considerably more involved through the need to take account of the d1 conditions (54) (for example in the form (iv)) – hence that i1 of introducing g_0, p jointly. It is then appropriate to introduce the quantities

$$(60)\qquad \gamma = \frac{p-1}{2} \in \widehat{\mathbb{Z}}$$

(N.B. since $p \in \widehat{\mathbb{Z}}^*$, its class in $\mathbb{Z}/2\mathbb{Z} = \widehat{\mathbb{Z}}/2\widehat{\mathbb{Z}}$ i2 is 1, hence $p-1 \in 2\widehat{\mathbb{Z}}$, whence the possibility of finding γ),

$$(61)\qquad h_0 = g_0^{-1}\sigma_\infty(g_0)$$

m772

Marginal note. m772 h_0, relative to the automorphism σ_∞ of order 2, plays a role symmetric to ξ relative to the automorphism ρ of order 3 – this does not show up either in the notation.

d2 We check indeed|thus that g is expressed by means of g_0 and of γ (hence of p) by means of the formula (equivalent to (54) (iv) or (v))

$$(62)\qquad \boxed{g = \sigma_\infty(g_0)\ell_1^\gamma\rho(g_0)^{-1}} \left(= (g_0\ell_0^{-\gamma}) \left(\underbrace{\ell_0^\gamma h_0}_{\xi} \right) \rho(g_0\ell_0^{-\gamma})^{-1} \right)$$

m773

Marginal note. m773 N.B. This expression for g is not changed if $g_0 \longmapsto g_0 \ell_0^{\alpha}$.

Thus the u that interest us are described by the pairs (g_0, γ) $(g_0 \in \widehat{\Pi}_{0,3}/L_0,\ \gamma \in \widehat{\mathbb{Z}})$ satisfying the conditions

$$(63) \qquad 2\gamma + 1 \in \widehat{\mathbb{Z}}^* \qquad (\text{NB} \quad 2\gamma + 1 = p = \chi(u))$$

and condition (51), where g is expressed as a function of g_0 and of γ by (62). This d3relationi3 (51) is in turn equivalent to the relation

$$(64) \qquad \boxed{\xi \rho(\xi) \rho^2(\xi) = 1}$$

where

$$(65) \quad \xi = \ell_0^{\gamma} h_0 \qquad \dagger|\text{with (66)} \qquad \begin{aligned} h_0 &\overset{\text{dfn}}{=} g_0^{-1} \sigma_\infty(g_0) \\ &= [g_0^{-1}, \sigma_\infty] \end{aligned}$$

m774

Marginal note. m774 N.B. We call h_0 here what we previously denoted by h_0^{-1}.

[scan 101]

Thus, the u are parametrized by the pairs $(g_0 \in \widehat{\Pi}_{0,3}/L_0,\ \gamma \in \widehat{\mathbb{Z}})$, satisfying conditions (63) and (64), which (by means of (65)) is written in explicit form

$$\boxed{(\ell_0^{\gamma} \underbrace{g_0^{-1} \sigma_\infty(g_0)}_{h_0}) \rho (\ell_0^{\gamma} \underbrace{g_0^{-1} \sigma_\infty(g_0)}_{h_0}) \rho^2 (\ell_0^{\gamma} \underbrace{g_0^{-1} \sigma_\infty(g_0)}_{h_0}) = 1} \qquad (65\text{bis})$$

m775

Marginal note. [m775] it would be better to regard this equation as an "equation in h_0" playing a role symmetric to "the equation in ξ" (68)

("equation in g_0" — as opposed to the "equation in ξ" below). (Moreover, we must add the preliminary condition, for the record...)

We can also consider that [d1] u (via g) is defined by ($\xi \in \widehat{\Pi}_{0,3},\ \gamma \in \widehat{\mathbb{Z}}$), which indeed allow us to recover

$$h_0 = \ell_0^{-\gamma}\xi$$

by (65), then g_0 by (66)

$$g_0^{-1}\sigma_\infty(g_0) = h_0$$

which indeed determines g_0 uniquely, thanks to the fact (which we admit provisionally) that $\widehat{\Pi}_{0,3}^{\sigma_\infty} = \{1\}$. The possibility of finding g_0 satisfying this condition is equivalent (we shall admit this here too) to the condition

$$\sigma_\infty(h_0)h_0 = 1 \tag{67}$$

which, in terms of ξ, γ, is also written in the form

Apparatus for this scan

`140-3-s101-D001` *deletion. Manuscript:* g is
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 102]

[p. 340]

$$\boxed{\sigma_\infty(\xi) = \ell_1^\gamma \xi^{-1} \ell_0^\gamma}. \tag{68}$$

Equations (64), (68) are called the "equations in ξ" — as opposed to the "equation in g_0" (66), which at first sight has the advantage of being a single one, and the disadvantage of being more complicated. In summary, the u that interest us ($u \in \mathrm{Aut}_{\mathrm{lac}}(\widehat{\mathfrak{S}}_{0,3}^+, \sigma_\infty)'$) are given|described by the pairs [d1]($\xi \in \widehat{\Pi}_{0,3}^+,\ \gamma \in \widehat{\mathbb{Z}}$)[i1], satisfying the conditions

rather "the equation in h_0"

$$\begin{aligned} &\text{a)} \quad 2\gamma + 1 \in \widehat{\mathbb{Z}}^* && (63)\\ &\text{b)} \quad \xi\rho(\xi)\rho^2(\xi) = 1 && (64)\\ &\text{c)} \quad \sigma_\infty(\xi) = \ell_1^\gamma \xi^{-1} \ell_0^\gamma && (68) \end{aligned}$$

d) Preliminary condition for the record (53) (which apparently are not expressed directly in a convenient way in terms of ξ, γ).

For two pairs (ξ, γ), (ξ', γ') to define the same u, it is necessary and sufficient that we have

$$\gamma = \gamma', \qquad \xi' = \ell_0^{-\alpha}\xi\ell_1^\alpha \qquad (\alpha \in \widehat{\mathbb{Z}}). \tag{69}$$

Condition (64) can also be replaced by a parametric representation

$$\begin{cases} \xi = \lambda\rho(\lambda)^{-1} & \text{or} \\ \xi = \lambda\ell_0^{-1}\rho(\lambda)^{-1} \end{cases} \tag{70}$$

with $\lambda \in \widehat{\Pi}_{0,3}$ — in which case equation (68)

Apparatus for this scan

140-3-s102-D001 *deletion. Manuscript:* (ξ, γ)
Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

Text: insertion integrated Reason: Explicit authorial insertion: integrated at the position recorded by the transcription, without changing its reading.

[scan 103]

can be interpreted as an "equation in λ", which according to the two cases takes the form

$$\begin{cases} \sigma_\infty(\lambda\rho(\lambda)^{-1}) = \ell_1^\gamma(\rho(\lambda)\lambda^{-1})\ell_0^\gamma \\ \qquad\qquad \text{or} \\ \sigma_\infty(\lambda\ell_0^{-1}\rho(\lambda)^{-1}) = \ell_1^\gamma(\rho(\lambda)\ell_0\lambda^{-1})\ell_0^\gamma, \end{cases} \tag{71}$$

Here for (λ, γ) and (λ', γ') to define the same u, it is necessary and sufficient that we have [d1]

$$\lambda' = \ell_0^{-\alpha}\lambda, \qquad \gamma = \gamma'. \tag{72}$$

Remarks 1) Up to the "harmless" factor ℓ_0^γ, which|that distinguishes h_0 and ξ (65), we can say that the search for the $u \in \mathrm{Aut}_{\mathrm{lac}}(\widehat{\mathfrak{S}}^{+}_{0,3}, \sigma_\infty)$ is equivalent to that for the [d2] simultaneous solutions of the two cocycle equations

$$\begin{cases} \xi\rho(\xi)\rho^2(\xi) = 1 \\ h_0\sigma_\infty(h_0) = 1 \end{cases} \tag{73}$$

relative [d3] to the groups $\mathbb{Z}/3\mathbb{Z}$, operating on $\widehat{\Pi}_{0,3}$ via ρ, and $\mathbb{Z}/2\mathbb{Z}$, operating via σ_∞ — whose solutions in parametric forms are respectively

$$\begin{cases} \xi = \lambda\rho(\lambda)^{-1} \quad \text{or} \quad \xi = \lambda\ell_0^{-1}\rho(\lambda)^{-1} \\ \qquad (\text{according as } \gamma \equiv 0\ (3) \text{ or } \gamma \equiv 1|-1\ (3) \\ \qquad\quad \text{i.e. } p \equiv 1\ (3) \text{ or } p \equiv -1\ (3)) \\ h_0 = |\equiv g_0^{-1}\sigma_\infty(g_0) \end{cases} \tag{74}$$

m777

Marginal note. [m777] N.B. expression (62) for g brings out equally well this double intervention of σ_∞ and of ρ in the determination of the u!!!

m778

Marginal note. [m778] (N.B. we could put everywhere g_0 for g_0^{-1}...)

[scan 105]

Let us note in this connection the equivalent conditions

$$\begin{cases} \text{(i)} & p = 1 \\ \text{(ii)} & \gamma = 0 \\ \text{(iii)} & g = \sigma_\infty(g_0)\rho(g_0)^{-1} \\ \text{(iv)} & h_0 = \xi \\ \text{(v)} & \sigma_\infty(\xi) = \xi^{-1} \qquad (\text{“equation in } \xi\text{” simplified!}) \\ \text{(vi)} & h_0 \rho(h_0) \rho^2(h_0) = 1 \end{cases} \tag{75bis}$$

all meaning that $\chi(u) = 1$. Thus the search for the $u \in \mathrm{Aut}_{\mathrm{lac}}(\widehat{\mathfrak{S}}^+_{0,3}, \sigma_\infty)'$ with multiplier 1 ($u \in \mathrm{Aut}_{\mathrm{lac}}(\widehat{\mathfrak{S}}^+_{0,3}, \sigma_\infty)'^0$) is thus indeed equivalent to that for the simultaneous solutions of the equations of cocycles[i1] (73), or of the parametric equations (“coboundary”) (74).

2) Returning to the general case (arbitrary multiplier), the only case that I know how to write down explicitly (except for $u = 1$)[i2] is the one that corresponds to $\tau_\infty \in \mathfrak{S}^*_{0,3}$, which corresponds to the characteristics

$$\begin{cases} u = \tau_\infty, \quad \chi(u) = p = -1, \quad \gamma = -1 \\ g = \ell_1^{-1} \\ g_0 = 1, \quad h_0 = 1, \quad \xi = \ell_0^{-1} \\ \lambda'_0 = 1, \quad \lambda' = \ell_0^\gamma g_0^{-1} \lambda_0 = \ell_0^{-1} \\ [\,\lambda_0 = \tau_\infty, \quad \lambda = \ell_0^{-1}\tau_\infty\,] \end{cases} \tag{75ter}$$

← cf. below

It would certainly be no luxury to manage to write down a bunch of other u, to see in particular whether the crowds|crowd of necessary conditions that we are led to derive for the elements coming from $\Gamma_{\mathbb{Q}}$, are not automatically satisfied!

[p. 342]

(VII) Calculations in $\mathrm{Sl}(2,\widehat{\mathbb{Z}})' = \mathrm{Sl}(2,\widehat{\mathbb{Z}})/\pm 1$ (cocycles under ρ).

m781

Marginal note. m781 Calculations "for conscience's sake", which will not be of use perhaps any more!

This group is a (very small!) quotient of $\widehat{\mathrm{Sl}(2,\mathbb{Z})'}$, which has the advantage of lending itself to convenient explicit algebraic[i1] calculations, in terms of matrices. Let us denote, by abuse of language, by the same letters $g, g_0, h_0, \xi, \lambda_0, \lambda$ elements of [d1] $\widehat{\Pi}_{0,3}$, (or of $\widehat{\mathfrak{S}}^+_{0,3}$ more generally)[i2] and their images in $\Pi(2)' \subset^{i3} \mathrm{Sl}(2,\widehat{\mathbb{Z}})'$ [d2] (or in $\mathrm{Gl}(2,\widehat{\mathbb{Z}})' \simeq \mathrm{Gl}(2,\widehat{\mathbb{Z}})/\{\pm 1\}$). [d3] [d4] in general, let us consider a matrix

$$g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{Gl}(2,\widehat{\mathbb{Z}}) \tag{76}$$

we then have

$$\begin{cases} \rho(g) = \rho g \rho^{-1} = \begin{pmatrix} c+d & -c \\ c+d-a-b & a-c \end{pmatrix}, \quad \det(g)\rho(g^{-1}) = \begin{pmatrix} a-c & c \\ a+b-c-d & c+d \end{pmatrix} \\ \rho^2(g) = \rho^{-1} g \rho = \begin{pmatrix} d-b & a+b-c-d \\ -b & a+b \end{pmatrix}, \quad \det(g)\rho^2(g^{-1}) = \begin{pmatrix} a+b & c+d-a-b \\ b & d-b \end{pmatrix} \end{cases} \tag{77}$$

$$\begin{cases} [g,\rho] = g\rho g^{-1}\rho^{-1} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}. \\ \delta A = (a^2+b^2+ab) - (ac+bd+bc) \qquad \delta B = ac+bd+bc \\ \delta C = -(c^2+d^2+cd) + (ac+bd+ad) \quad \delta D = c^2+d^2+cd \end{cases} \tag{78}$$

m782

Marginal note. [m782] N.B. $C + D - B = 1 \quad \delta = \det g = ad - bc$ [d10]

We shall write the equation

$$g\rho(g)\rho^2(g) = 1$$

in the equivalent form

$$(79) \qquad g\rho(g) = \rho^{-1}(g^{-1})(= \rho^2(g^{-1})) \qquad \underline{\text{in } \mathrm{Gl}(2, \widehat{\mathbb{Z}})'}$$

where

$$(80) \qquad g\rho(g) = \begin{pmatrix} P & Q \\ R & S \end{pmatrix}$$

$$(81)\qquad \begin{cases} P=(a+b)(c+d-b) & Q=-a(c-b)-bc=\delta-a(c+d-b) \\ R=(c+d)^2-d(a+b) & S=ad-c(c+d)=\underset{\text{if } \det g=1}{\delta}-c(c+d-b) \\ \underset{\text{if } \det g=+1}{=}(c+d)(c+d-b)-\delta & \end{cases}$$

where we have set $\delta = ad - bc = \det g$.

Comparing (81) and the expression (77) for $\rho^2(g^{-1})$, equation (79) – which is also written

$$g\rho(g) = \pm\rho^2(g^{-1})$$

gives the following solutions.

m783

Marginal note. m783 Up to replacing g by $-g$, d3 we are reduced to determining the solutions of the equation

$$(82)\qquad g|\rho\rho(g)\rho^2(g) = +|\pm 1 \qquad \text{i.e.} \quad g|\rho\rho(g) = +|\pm\rho^{-1}(g^{-1}) \qquad \underline{\text{in } \mathrm{Gl}(2,\widehat{\mathbb{Z}})}$$

d4 We distinguish the solutions according to the factors of the product

$$\mathrm{Sl}(2,\widehat{\mathbb{Z}})' \simeq \prod_{\ell \text{ premier}} \mathrm{Sl}(2,\mathbb{Z}_\ell)'.$$

m784

Marginal note. m784 N.B. We shall use|use this study of equation (82) only in the case $\det g = 1$, i.e. $\delta = 1$, unless I am mistaken

The relation

$$\frac{1}{\delta}(a+b) = P = (a+b)(c+d-b) \qquad \text{in } \mathbb{Z}_\ell$$

gives the two solutions $a + b = 0$ or $c + d - b = 1$ (since $\mathbb{Z}_\ell$ is an integral domain).

d5

m785

Marginal note. m785 The necessity of this formula (84) was obvious a priori.

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

140-3-s107-D005 *deletion. Manuscript:* 1°) $(a+b) \neq 0$ (in $\mathbb{Z}_\ell$) whence $c+d-b=1$

$$(83) \qquad \boxed{c+d-b = \frac{1}{\delta}}.$$

Given (83), we verify at once that the formulas $g\rho(g) = \rho^{-1}(g^{-1})$ – which remain to be checked

$$P = (a+b)/\delta \quad Q = (1-a)/\delta$$
$$R = b/\delta \qquad\quad S = (1-c)/\delta$$

[illeg. 1] $R =$

$$Q = \frac{c+d-a-b}{\delta}\left(= \frac{1}{\delta^2}|\frac{1}{\delta} - \frac{a}{\delta}\right),$$
$$R = \frac{b}{\delta}, \quad S = \frac{d-b}{\delta}\left(= \frac{1}{\delta^2} - \frac{c}{\delta}\right)$$

(84) are equivalent to [illeg. 5] (82) [illeg. 1]

$$(84) \qquad \boxed{\delta^3 = 1}.$$

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

140-3-s107-D007 *deletion. Manuscript:* 2°) $a+b=0$ i.e. $a=-b$, i.e. $g = \begin{pmatrix} -b & b \\ c & d \end{pmatrix}$, and

$$-b(c+d) = 1$$

$$(84) \quad \begin{cases} \det g = -b(c+d) = \delta \quad (\text{thus } \delta + b(c+d) = 0;) \\ d = -\frac{\delta}{b} - c \\ P = 0, \\ Q = \delta + b(c+d-b) = -b^2 \\ R = (c+d)^2 = \frac{\delta^2}{b^2}, \\ S = ad \ [illeg.\ 1] \\ -c(c+d) + ad = 1 - c(c+d-b) \\ [illeg.\ 1] c = \delta + c\left(\frac{\delta}{b} + b\right) \end{cases}$$

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 108]

[p. 343]

1°) $a+b\neq 0$ (in $\mathbb{Z}_\ell$) whence

$$(83)\qquad \boxed{c+d-b=\frac{1}{\delta}}.$$

Given (83), we verify that the formulas (82), – where it remains to check

$$Q=\frac{c+d-(a+b)}{\delta}\ \leftarrow\ |=\left(=\frac{1}{\delta^2}-\frac{a}{\delta}\right),\quad R=\frac{b}{\delta}$$
$$S=\frac{d-b}{\delta}.\ \left(=\frac{1}{\delta^2}-\frac{c}{\delta}\right)$$

are equivalent to:

$$(84)\qquad \boxed{\delta^3=1}$$

(whose necessity was obvious a priori).

m786

Marginal note. m786 N.B. The conditions $c+d-b=\frac{1}{\delta}$, $\delta^3=1$ are sufficient [illeg. 1] for equations (82), ! (independently of the question whether $a+b=0$ or $a+b\neq 0$) – they are necessary if we assume that we are not in case 2° below

2°) $a+b=0$ (in $\mathbb{Z}_\ell$) whence

$$(85)\qquad a=-b\qquad \text{i.e.}\quad g=\begin{pmatrix}-b & b\\ c & d\end{pmatrix}$$

$$(86)\qquad \begin{cases}\det g=-b(c+d)=\delta & \text{whence}\\ \delta+b(c+d)=0 & d=-\dfrac{\delta}{b}-c\end{cases}$$

i.e.

$$g=\begin{pmatrix}-b & b\\ c & -\frac{\delta}{b}-c\end{pmatrix},$$

and

$$\begin{cases}P=0, & Q=\delta+b(c+d-b)=-b^2\\ R=(c+d)^2=\dfrac{\delta^2}{b^2}, & S=\delta+c\left(\dfrac{\delta}{b}+b\right);\end{cases}$$

d2

$$\rho^2(g^{-1})=\begin{pmatrix}0 & -1/b\\ b/\delta & -\frac{1}{\delta}\left(\frac{\delta}{b}+b+c\right)\end{pmatrix},$$

d3

and equation (82) is then written

$$(87)\qquad \begin{cases}\text{a)} & b^3=\delta^3=1.\\ \text{b)} & c((b\delta)^2+(b\delta)+1)+(\delta^2+b^2\delta+b)=0.\end{cases}$$

Text: omitted Reason: Cancelled in the manuscript: omission follows the author's final state; uncertainty in the cancelled material remains marked.

[scan 109]

We again distinguish two cases:

a) $b\delta = 1$ i.e. $b = \frac{1}{\delta}$, then equation 87 b)[i1] becomes

$$3c + 3\frac{1}{\delta} = 0 \qquad \text{i.e.}$$

d1

$$(88) \qquad c = -\frac{1}{\delta} = -\delta^2$$

[d4] corresponds to

$$(90) \qquad g = \begin{pmatrix} -\delta' & \delta' \\ -\delta' & 0 \end{pmatrix}$$

where $\delta' = 1/\delta = \delta^2$, and[i4] where, I recall, δ is subject to the sole condition

$$\delta^3 = 1.$$

b) $b\delta \neq 1$ thus (since $(b\delta)^3 = 1$) $(b\delta)^2 + b\delta + 1 = 0$) and equation (87 b) becomes

$$(\alpha) \qquad \delta^2 + b^2\delta + b = 0.$$

We shall have

$$\begin{cases} b = u\frac{1}{\delta} = u\delta^2 \quad \text{with} \quad u^3 = 1,\ u \neq 1 \qquad \text{i.e.} \\ u^2 + u + 1 = 0 \end{cases}$$

and equation α), [d12] reduces to

$$u^2|\delta^2 + u + 1 = 0.$$

d1 $= \begin{pmatrix} 0 & -1|+1 \\ 1 & -1 \end{pmatrix}$ i1

Remarks[i2] [d2] 1°) Obviously $-\rho$ is also a solution of (87) (just like ρ^{-1}) [d3] (just like $-\rho^{-1}$), but it falls respectively under cases [d4] 1°) [d5] [d6]

2°) To [d7]determine[i3] the solutions in $\mathrm{Gl}(2,\widehat{\mathbb{Z}})$ of $g\rho(g)\rho^2(g)=1$, it suffices to choose for $\forall\,\ell$ such a solution in $\mathrm{Gl}(2,\widehat{\mathbb{Z}})$, using the result|results (86); we shall note that the "cases" obtained 1°) to 3°) can vary from one ℓ to another. [d8] We should keep in mind that cases 1°), 2°), 3°) correspond resp.[t] to families of solutions depending on 2, 1 and 0 parameters.

3°) I do not know whether a $\xi \in \mathrm{Sl}(2,\widehat{\mathbb{Z}})'|*$, $\xi = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ [i4], which satisfies[i5] $g\rho(g)\rho^2(g) = 1$ admits a parametric representation of the form (58) by $\lambda_0\rho(\lambda_0)^{-1}$ or $\lambda_0'(-l_1^{-1})\rho(\lambda_0')^{-1} = \lambda_0(-l_1^{-1}|l_0^{-1})\rho(\lambda_0)^{-1}$ with $\lambda_0 = \lambda_0'\tau_\infty$ [i6] (it suffices to look separately in the $\mathrm{Sl}(2,\mathbb{Z}_\ell)'$). I do not know even if we assume $g \equiv \mathrm{id}\ (2)$, (which is a condition on the component in $\mathrm{Sl}(2,\mathbb{Z}_2)'$ only). We see in

m787

Marginal note. [m787] N.B. $g = l_0^{-1}$ is not a solution of this the equation|equation, on the other hand $g = -l_0^{-1}$ is…
